Abstract

Physical geometry studies mutual disposition of geometrical objects and points in space, or space-time, which is described by the distance function d, or by the world function $\sigma = d^2/2$. One suggests a new general method of the physical geometry construction. The proper Euclidean geometry is described in terms of its world function σ_{E}. Any physical geometry $\mathcal{G}$ is obtained from the Euclidean geometry as a result of replacement of the Euclidean world function σ_{E} by the world function σ of $\mathcal{G}$. This method is very simple and effective. It introduces a new geometric property: nondegeneracy of geometry. Using this method, one can construct deterministic space-time geometries with primordially stochastic motion of free particles and geometrized particle mass. Such a space-time geometry defined properly (with quantum constant as an attribute of geometry) allows one to explain quantum effects as a result of the statistical description of the stochastic particle motion (without a use of quantum principles).

1 Introduction

A geometry lies in the foundation of physics, and a true conception of geometry is very important for the consequent development of physics. It is common practice to think that all problems in foundations of geometry have been solved many years ago. It is valid, but this concerns the geometry considered to be a logical construction. Physicists are interested in the geometry considered as a science on mutual disposition of geometrical objects in the space or in the space-time. The two aspects of geometry are quite different, and one can speak about two different geometries, using for them two different terms. Geometry as a logical construction is a homogeneous geometry, where all points have the same properties. Well known mathematician Felix Klein [1] believed that only the homogeneous geometry deserves to be called a geometry. It is his opinion that the Riemannian geometry (in general, inhomogeneous geometry) should be qualified as a Riemannian geography, or a Riemannian topography. In other words, Felix Klein considered a geometry mainly as a logical construction. We shall refer to such a geometry as the mathematical geometry.

The geometry considered to be a science on mutual disposition of geometric objects will be referred to as a physical geometry, because the physicists are interested mainly in this aspect of a geometry. The physical geometries are inhomogeneous, in general, although they may be homogeneous also. On the one hand, the proper Euclidean geometry is a physical geometry. On the other hand, it is a logical construction, because it is homogeneous and can be constructed of simple elements (points, straights, planes, etc.). All elements of the Euclidean geometry have similar properties, which are described by axioms. Similarity of geometrical elements allows one to construct the mathematical (homogeneous) geometry by means of logical reasonings. The proper Euclidean geometry was constructed many years ago by Euclid. Consistency of this construction was investigated and proved in [2]. Such a construction is very complicated even in the case of the proper Euclidean geometry, because simple geometrical objects are used for construction of the more complicated ones, and one cannot construct a complicated geometrical object $\mathcal{O}$ without construction of the more simple constituents of this object.

Note that constructing his geometry, Euclid did not use coordinates for labeling of the space points. His description of the homogeneous geometry was coordinateless. It means that the coordinates are not a necessary attribute of the geometry. Coordinate system is a method of the geometry description, which may or may not be used. Application of coordinates and of other means of description poses the problem of separation of the geometry properties from the properties of the means of the description. Usually the separation of the geometry properties from the coordinate system properties is carried out as follows. The geometry is described in all possible coordinate systems. Transformations from one coordinate system to the another one form a group of transformation. Invariants of this transformation group are the same in all coordinate system, and hence, they describe properties of the geometry in question.

At this point we are to make a very important remark. *Any geometry is a totality of all geometric objects $\mathcal{O}$ and of all relations $\mathcal{R}$ between them.* Any geometric object $\mathcal{O}$ is a subset of points of some point set Ω, where the geometry is given. In the Riemannian geometry (and in other inhomogeneous geometries) the set Ω is supposed to be a n-dimensional manifold, whose points P are labelled by n coordinates $x = \{x^1, x^2, ...x^n\}$. This labelling (arithmetization of space) is considered to be a necessary attribute of the Riemannian geometry. Most geometers believe that the Riemannian geometry (and physical geometry), in general cannot be constructed without introduction of the manifold. In other words, they believe that the manifold is an attribute of the Riemannian geometry (and of any continuous geometry, in general). This belief is founded on the fact, that the Riemannian geometry is always constructed on some manifold. But this belief is a delusion. The fact, that we always construct the physical geometry on some manifold, does not mean that the physical geometry cannot be constructed without a reference to a manifold, or to a coordinate system. Of course, some labelling of the spatial points (coordinate system) is convenient, but this labelling has no relations to the construction of the geometry, and the physical geometry should be constructed without a reference to coordinate system. Application of the coordinate system imposes constraints on properties of the constructed physical geometry. For instance, if we use a continuous coordinate system (manifold) we can construct only continuous physical geometry. To construct a discrete physical geometry, the geometry construction is not to contain a reference to the coordinate system.

Here we present the method of the physical geometry construction, which does not contain a reference to the coordinate system and other means of description. It contains a reference only to the distance function d, which is a real characteristic of physical geometry.

If a geometry is inhomogeneous, and the straights located in different places have different properties, it is impossible to describe properties of straights by means of axioms, because there are no such axioms for the whole geometry. Mutual disposition of points in a physical (inhomogeneous) geometry, which is given on the set Ω of points P, is described by the distance function $d(P,Q)$

$$d: \qquad \Omega\times\Omega\rightarrow\mathbf{R}, \qquad d(P,P)=0, \qquad \forall P\in\Omega \tag{1.1}$$

where $\mathbf{R}$ denotes the set of all real numbers. The distance function d is the main characteristic of the physical geometry. Besides, the distance function d is an *unique characteristic* of any physical geometry. *The distance function d determines completely the physical geometry, and one does not need any additional information for determination of the physical geometry.* This statement is very important for construction of a physical geometry. It will be proved below. Any physical geometry $\mathcal{G}$ is constructed on the basis of the proper Euclidean geometry $\mathcal{G}_{\mathrm{E}}$ by means of a deformation, i.e. by a replacement of the Euclidean distance function d_{E} by the distance function of the geometry in question. For instance, constructing the Riemannian geometry, we replace the Euclidean infinitesimal distance $dS_{\mathrm{E}}=\sqrt{g_{\mathrm{E}ik}dx^{i}dx^{k}}$ by the Riemannian one $dS=\sqrt{g_{ik}dx^{i}dx^{k}}$. There is no method of the inhomogeneous physical geometry construction other, than the deformation of the Euclidean geometry (or some other homogeneous geometry) which is constructed as a mathematical geometry on the basis of its axiomatics and logic. Unfortunately, conventional method of the Riemannian geometry construction contains a reference to the coordinate system. But this reference can be eliminated, provided that we use finite distances d instead of infinitesimal distances dS.

For description of a physical geometry one uses the world function σ [3], which is connected with the distance function d by means of the relation $\sigma(P,Q)=\frac{1}{2}d^{2}(P,Q)$. The world function σ of the σ-space $V=\{\sigma,\Omega\}$ is defined by the relation

$$\sigma : \qquad \Omega \times \Omega \rightarrow \mathbf{R}, \qquad \sigma(P,P) = 0, \qquad \forall P \in \Omega \tag{1.2}$$

where $\mathbf{R}$ denotes the set of all real numbers. Application of the world function is more convenient in the relation that the world function is real, when the distance function d is imaginary and does not satisfy definition (1.1). It is important at the consideration of the space-time geometry as a physical geometry.

In general, a physical geometry cannot be constructed as a logical building, because any change of the world function should be accompanied by a change of axiomatics. This is practically aerial, because the set of possible physical geometries is continual. Does the world function contain full information which is necessary for construction of the physical geometry? It is a very important question. For instance, can one derive the space dimension from the world function in the case of Euclidean geometry? Slightly below we shall answer this question in the affirmative. Now we formulate the method of the physical geometry construction.

Let us imagine that the proper Euclidean geometry $\mathcal{G}_{\mathrm{E}}$ can be described completely in terms and only in terms of the Euclidean world function σ_{E}. Such a description is called σ-immanent. It means that any geometrical object $\mathcal{O}_{\mathrm{E}}$ and any relation $\mathcal{R}_{\mathrm{E}}$ between geometrical objects in $\mathcal{G}_{\mathrm{E}}$ can be described in terms of σ_{E} in the form $\mathcal{O}_{\mathrm{E}}(\sigma_{\mathrm{E}})$ and $\mathcal{R}_{\mathrm{E}}(\sigma_{\mathrm{E}})$. To obtain corresponding geometrical object $\mathcal{O}$ and corresponding relation $\mathcal{R}$ between the geometrical objects in other physical geometry $\mathcal{G}$, it is sufficient to replace the Euclidean world function σ_{E} by the world function σ of the physical geometry $\mathcal{G}$ in description of $\mathcal{O}_{\mathrm{E}}(\sigma_{\mathrm{E}})$ and $\mathcal{R}_{\mathrm{E}}(\sigma_{\mathrm{E}})$.

$$\mathcal{O}_{\mathrm{E}}(\sigma_{\mathrm{E}}) \rightarrow \mathcal{O}_{\mathrm{E}}(\sigma), \qquad \mathcal{R}_{\mathrm{E}}(\sigma_{\mathrm{E}}) \rightarrow \mathcal{R}_{\mathrm{E}}(\sigma)$$

Index 'E' shows that the geometric object is constructed on the basis of the Euclidean axiomatics. Thus, one can obtain another physical geometry $\mathcal{G}$ from the Euclidean geometry $\mathcal{G}_{\mathrm{E}}$ by a simple replacement of σ_{E} by σ. For such a construction one needs no axiomatics and no reasonings. One needs no means of descriptions (topological structures, continuity, coordinate system, manifold, dimension, etc.). In fact, one uses implicitly the axiomatics of the Euclidean geometry, which is deformed by the replacement $\sigma_{\mathrm{E}} \rightarrow \sigma$. This replacement may be interpreted as a deformation of the Euclidean space. Absence of a reference to the means of description is an advantage of the considered method of the geometry construction. Besides, there is no necessity to construct the whole geometry $\mathcal{G}$. We can construct and investigate only that part of the geometry $\mathcal{G}$ which we are interested in. Any physical geometry may be constructed as a result of a deformation of the Euclidean geometry.

The geometric object $\mathcal{O}$ is described by means of the skeleton-envelope method [4]. It means that any geometric object $\mathcal{O}$ is considered to be a set of intersections and joins of elementary geometric objects (EGO).

The finite set $\mathcal{P}^n \equiv \{P_0, P_1, ..., P_n\} \subset \Omega$ of parameters of the envelope function $f_{\mathcal{P}^n}$ is the skeleton of elementary geometric object (EGO) $\mathcal{E} \subset \Omega$. The set $\mathcal{E} \subset \Omega$ of points forming EGO is called the envelope of its skeleton $\mathcal{P}^n$. For continuous physical geometry the envelope $\mathcal{E}$ is usually a continual set of points. The envelope function $f_{\mathcal{P}^n}$, determining EGO is a function of the running point $R \in \Omega$ and of parameters $\mathcal{P}^n \subset \Omega$. The envelope function $f_{\mathcal{P}^n}$ is supposed to be an algebraic function of s arguments $w = \{w_1, w_2, ...w_s\}$, $s = (n+2)(n+1)/2$. Each of arguments $w_k = \sigma(Q_k, L_k)$ is a σ-function of two arguments $Q_k, L_k \in \{R, \mathcal{P}^n\}$, either belonging to skeleton $\mathcal{P}^n$, or coinciding with the running point R. Thus, any elementary geometric object $\mathcal{E}$ is determined by its skeleton and its envelope function.

For instance, the sphere $\mathcal{S}(P_0, P_1)$ with the center at the point P_0 is determined by the relation

$$\mathcal{S}(P_0, P_1) = \{R | f_{P_0 P_1}(R) = 0\}, \qquad f_{P_0 P_1}(R) = \sqrt{2\sigma(P_0, P_1)} - \sqrt{2\sigma(P_0, R)} \quad (1.3)$$

where P_1 is a point belonging to the sphere. The elementary object $\mathcal{E}$ is determined in all physical geometries at once. In particular, it is determined in the proper Euclidean geometry, where we can obtain its meaning. We interpret the elementary geometrical object $\mathcal{E}$, using our knowledge of the proper Euclidean geometry. Thus, the proper Euclidean geometry is used as a sample geometry for interpretation of any physical geometry.

We do not try to repeat subscriptions of Euclid at construction of the geometry. We take the geometrical objects and relations between them, prepared in the framework of the Euclidean geometry and describe them in terms of the world function. Thereafter we deform them, replacing the Euclidean world function σ_{E} by the world function σ of the geometry in question. In practice the construction of the elementary geometry object is reduced to the representation of the corresponding Euclidean geometrical object in the σ-immanent form, i.e. in terms of the Euclidean world function. The last problem is the problem of the proper Euclidean geometry. The problem of representation of the geometrical object (or relation between objects) in the σ-immanent form is a real problem of the physical geometry construction.

It is very important, that such a construction does not use coordinates and other methods of description, because the application of the means of description imposes constraints on the constructed geometry. Any means of description is a structure St given on the basic Euclidean geometry with the world function σ_{E}. Replacement $\sigma_{\mathrm{E}} \rightarrow \sigma$ is sufficient for construction of unique physical geometry $\mathcal{G}_\sigma$. If we use an additional structure St for construction of physical geometry, we obtain, in general, other geometry $\mathcal{G}_{St}$, which coincide with $\mathcal{G}_\sigma$ not for all σ, but only for some of world functions σ. Thus, a use of additional means of description restricts the list of possible physical geometries. For instance, if we use the coordinate description at construction of the physical geometry, the obtained geometry appears to be continuous, because description by means of the coordinates is effective only for continuous geometries, where the number of coordinates coincides with the geometry dimension.

Constructing geometry $\mathcal{G}$ by means of a deformation we use essentially the fact that the proper Euclidean geometry $\mathcal{G}_{\mathrm{E}}$ is a mathematical geometry, which has been constructed on the basis of Euclidean axiomatics and logical reasonings.

We shall refer to the described method of the physical geometry construction as the deformation principle and interpret the deformation in the broad sense of the word. In particular, a deformation of the Euclidean space may transform an Euclidean surface into a point, and an Euclidean point into a surface. Such a deformation may remove some points of the Euclidean space, violating its continuity, or decreasing its dimension. Such a deformation may add supplemental points to the Euclidean space, increasing its dimension. In other words, the deformation principle is a very general method of the physical geometry construction.

The deformation principle as a method of the physical geometry construction contains two essential stages:

(i) Representation of geometrical objects $\mathcal{O}$ and relations $\mathcal{R}$ of the Euclidean geometry in the σ-immanent form, i.e. in terms and only in terms of the world function σ_{E}.

(ii) Replacement of the Euclidean world function σ_{E} by the world function σ of the geometry in question.

A physical geometry, constructed by means of the only deformation principle (i.e. without a use of other methods of the geometry construction) is called T-geometry (tubular geometry) [5, 4, 6]. The T-geometry is the most general kind of the physical geometry.

Application of the deformation principle is restricted by two constraints.

1. Describing Euclidean geometric objects $\mathcal{O}(\sigma_{\mathrm{E}})$ and Euclidean relation $\mathcal{R}(\sigma_{\mathrm{E}})$ in terms of σ_{E}, we are not to use special properties of Euclidean world function σ_{E}. In particular, definitions of $\mathcal{O}(\sigma_{\mathrm{E}})$ and $\mathcal{R}(\sigma_{\mathrm{E}})$ are to have similar form in Euclidean geometries of different dimensions. They must not depend on the dimension of the Euclidean space.

2. The deformation principle is to be applied separately from other methods of the geometry construction. In particular, one may not use topological structures in construction of a physical geometry, because for effective application of the deformation principle the obtained physical geometry must be determined only by the world function (metric).

2 Description of the proper Euclidean space in terms of the world function

The crucial point of the T-geometry construction is the description of the proper Euclidean geometry in terms of the Euclidean world function σ_{E}. We shall refer to this method of description as the σ-immanent description. Unfortunately, it was unknown for many years, although all physicists knew that the infinitesimal interval $dS = \sqrt{g_{ik}dx^i dx^k}$ is the unique essential characteristic of the space-time geometry, and changing this expression, we change the space-time geometry. From physical viewpoint the σ-immanent description is very reasonable, because it does not contain any extrinsic information. The σ-immanent description does not refer to the means of description (dimension, manifold, coordinate system). Absence of references to means of description is important in the relation, that there is no necessity to separate the information on the geometry in itself from the information on the means of description. The σ-immanent description contains only essential characteristic of geometry: its world function. At first the σ-immanent description was obtained in 1990 [5].

The first question concerning the σ-immanent description is as follows. Does the world function contain sufficient information for description of a physical geometry? The answer is affirmative, at least, in the case of the proper Euclidean geometry, and this answer is given by the prove of the following theorem.

Let σ-space $V = \{\sigma, \Omega\}$ be a set Ω of points P with the given world function σ

$$\sigma : \qquad \Omega \times \Omega \rightarrow \mathbf{R}, \qquad \sigma(P,P) = 0, \qquad \forall P \in \Omega \tag{2.1}$$

where $\mathbf{R}$ denotes the set of all real numbers. Let the vector $\mathbf{P}_0\mathbf{P}_1 = \{P_0, P_1\}$ be the ordered set of two points P_0, P_1, and its length $|\mathbf{P}_0\mathbf{P}_1|$ is defined by the relation $|\mathbf{P}_0\mathbf{P}_1|^2 = 2\sigma(P_0, P_1)$.

Theorem

The σ-space $V = \{\sigma, \Omega\}$ is the n-dimensional proper Euclidean space, if and only if the world function σ satisfies the following conditions, written in terms of the world function σ.

I. Condition of symmetry:

$$\sigma(P,Q) = \sigma(Q,P), \qquad \forall P, Q \in \Omega \tag{2.2}$$

II. Definition of the dimension:

$$\exists \mathcal{P}^n \equiv \{P_0, P_1, ...P_n\}, \qquad F_n(\mathcal{P}^n) \neq 0, \qquad F_k\left(\Omega^{k+1}\right) = 0, \qquad k > n \tag{2.3}$$

where $F_n(\mathcal{P}^n)$ is the Gram's determinant

$$F_n(\mathcal{P}^n) = \det ||(\mathbf{P}_0\mathbf{P}_i.\mathbf{P}_0\mathbf{P}_k)|| = \det ||g_{ik}(\mathcal{P}^n)||, \qquad i,k = 1,2,...n \tag{2.4}$$

The scalar product $(\mathbf{P}_0\mathbf{P}_1.\mathbf{Q}_0\mathbf{Q}_1)$ of two vectors $\mathbf{P}_0\mathbf{P}_1$ and $\mathbf{Q}_0\mathbf{Q}_1$ is defined by the relation

$$(\mathbf{P}_0\mathbf{P}_1.\mathbf{Q}_0\mathbf{Q}_1) = \sigma(P_0, Q_1) + \sigma(P_1, Q_0) - \sigma(P_0, Q_0) - \sigma(P_1, Q_1) \tag{2.5}$$

Vectors $\mathbf{P}_0\mathbf{P}_i$, $i = 1, 2, ...n$ are basic vectors of the rectilinear coordinate system K_n with the origin at the point P_0, and the metric tensors $g_{ik}(\mathcal{P}^n)$, $g^{ik}(\mathcal{P}^n)$, $i,k = 1,2,...n$ in K_n are defined by the relations

$$\sum_{k=1}^{k=n} g^{ik}(\mathcal{P}^n)\, g_{lk}(\mathcal{P}^n) = \delta_l^i, \qquad g_{il}(\mathcal{P}^n) = (\mathbf{P}_0\mathbf{P}_i.\mathbf{P}_0\mathbf{P}_l), \qquad i,l = 1,2,...n \tag{2.6}$$

III. Linear structure of the Euclidean space:

$$\sigma(P,Q) = \frac{1}{2} \sum_{i,k=1}^{i,k=n} g^{ik}(\mathcal{P}^n)\left(x_i(P) - x_i(Q)\right)\left(x_k(P) - x_k(Q)\right), \qquad \forall P, Q \in \Omega \tag{2.7}$$

where coordinates $x_i(P)$, $i = 1, 2, ...n$ of the point P are covariant coordinates of the vector $\mathbf{P}_0\mathbf{P}$, defined by the relation

$$x_i(P) = (\mathbf{P}_0\mathbf{P}_i.\mathbf{P}_0\mathbf{P}), \qquad i = 1, 2, ...n \tag{2.8}$$

IV: The metric tensor matrix $g_{lk}(\mathcal{P}^n)$ has only positive eigenvalues

$$g_k > 0, \qquad k = 1, 2, ..., n \tag{2.9}$$

V. The continuity condition: the system of equations

$$(\mathbf{P}_0\mathbf{P}_i.\mathbf{P}_0\mathbf{P}) = y_i \in \mathbf{R}, \qquad i = 1, 2, ...n \tag{2.10}$$

considered to be equations for determination of the point P as a function of coordinates $y = \{y_i\}$, $i = 1, 2, ...n$ has always one and only one solution. Conditions II – V contain a reference to the dimension n of the Euclidean space.

As far as the σ-immanent description of the proper Euclidean geometry is possible, it is possible for any T-geometry, because any geometrical object $\mathcal{O}$ and any relation $\mathcal{R}$ in the physical geometry $\mathcal{G}$ is obtained from the corresponding geometrical object $\mathcal{O}_{\mathrm{E}}$ and from the corresponding relation $\mathcal{R}_{\mathrm{E}}$ in the proper Euclidean geometry $\mathcal{G}_{\mathrm{E}}$ by means of the replacement $\sigma_{\mathrm{E}} \rightarrow \sigma$ in description of $\mathcal{O}_{\mathrm{E}}$ an $\mathcal{R}_{\mathrm{E}}$. For such a replacement be possible, the description of $\mathcal{O}_{\mathrm{E}}$ and $\mathcal{R}_{\mathrm{E}}$ is not to refer to special properties of σ_{E}, described by conditions II – V. A formal indicator of the conditions II – V application is a reference to the dimension n, because any of conditions II – V contains a reference to the dimension n of the proper Euclidean space.

If nevertheless we use one of special properties II – V of the Euclidean space in the σ-immanent description of a geometrical object $\mathcal{O}$, or relation $\mathcal{R}$, we refer to the dimension n and, ultimately, to the coordinate system, which is only a means of description.

Let us show this in the example of the determination of the straight in the n-dimensional Euclidean space. The straight $\mathcal{T}_{P_0Q}$ in the proper Euclidean space is defined by two its points P_0 and Q $(P_0 \neq Q)$ as the set of points R

$$\mathcal{T}_{P_0Q} = \{R \mid \mathbf{P}_0\mathbf{Q} || \mathbf{P}_0\mathbf{R}\} \tag{2.11}$$

where condition $\mathbf{P}_0\mathbf{Q}||\mathbf{P}_0\mathbf{R}$ means that vectors $\mathbf{P}_0\mathbf{Q}$ and $\mathbf{P}_0\mathbf{R}$ are collinear, i.e. the scalar product $(\mathbf{P}_0\mathbf{Q}.\mathbf{P}_0\mathbf{R})$ of these two vectors satisfies the relation

$$\mathbf{P}_0\mathbf{Q}||\mathbf{P}_0\mathbf{R}: \qquad (\mathbf{P}_0\mathbf{Q}.\mathbf{P}_0\mathbf{R})^2 = (\mathbf{P}_0\mathbf{Q}.\mathbf{P}_0\mathbf{Q})(\mathbf{P}_0\mathbf{R}.\mathbf{P}_0\mathbf{R}) \tag{2.12}$$

where the scalar product is defined by the relation (2.5). Thus, the straight line $\mathcal{T}_{P_0Q}$ is defined σ-immanently, i.e. in terms of the world function σ. We shall use two different names (straight and tube) for the geometric object $\mathcal{T}_{P_0Q}$. We shall use the term "straight", when we want to stress that $\mathcal{T}_{P_0Q}$ is a result of deformation of the Euclidean straight. We shall use the term "tube", when we want to stress that $\mathcal{T}_{P_0Q}$ may be a many-dimensional surface.

In the Euclidean geometry one can use another definition of collinearity. Vectors $\mathbf{P}_0\mathbf{Q}$ and $\mathbf{P}_0\mathbf{R}$ are collinear, if components of vectors $\mathbf{P}_0\mathbf{Q}$ and $\mathbf{P}_0\mathbf{R}$ in some coordinate system are proportional. For instance, in the n-dimensional Euclidean space one can introduce rectangular coordinate system, choosing $n+1$ points $\mathcal{P}^n = \{P_0, P_1, ...P_n\}$ and forming n basic vectors $\mathbf{P}_0\mathbf{P}_i$, $i = 1, 2, ...n$. Then the collinearity condition can be written in the form of n equations

$$\mathbf{P}_0\mathbf{Q}||\mathbf{P}_0\mathbf{R}: \qquad (\mathbf{P}_0\mathbf{P}_i.\mathbf{P}_0\mathbf{Q}) = a\,(\mathbf{P}_0\mathbf{P}_i.\mathbf{P}_0\mathbf{R})\,, \qquad i = 1, 2, ...n, \tag{2.13}$$

where a is some real constant. Relations (2.13) are relations for covariant components of vectors $\mathbf{P}_0\mathbf{Q}$ and $\mathbf{P}_0\mathbf{R}$ in the considered coordinate system with basic vectors $\mathbf{P}_0\mathbf{P}_i$, $i = 1, 2, ...n$. Let points $\mathcal{P}^n$ be chosen in such a way, that $(\mathbf{P}_0\mathbf{P}_1.\mathbf{P}_0\mathbf{Q}) \neq 0$. Then eliminating the parameter a from relations (2.13), we obtain $n-1$ independent relations, and the geometrical object

$$\mathcal{T}_{Q\mathcal{P}^n} = \{R \mid \mathbf{P}_0\mathbf{Q}||\mathbf{P}_0\mathbf{R}\} = \bigcap_{i=2}^{i=n} \mathcal{S}_i, \tag{2.14}$$

$$\mathcal{S}_i = \left\{ R \left| \frac{(\mathbf{P}_0\mathbf{P}_i.\mathbf{P}_0\mathbf{Q})}{(\mathbf{P}_0\mathbf{P}_1.\mathbf{P}_0\mathbf{Q})} = \frac{(\mathbf{P}_0\mathbf{P}_i.\mathbf{P}_0\mathbf{R})}{(\mathbf{P}_0\mathbf{P}_1.\mathbf{P}_0\mathbf{R})} \right. \right\}, \qquad i = 2, 3, ...n \tag{2.15}$$

defined according to (2.13), depends on $n+2$ points $Q, \mathcal{P}^n$. This geometrical object $\mathcal{T}_{Q\mathcal{P}^n}$ is defined σ-immanently. It is a complex, consisting of the straight line and the coordinate system, represented by $n+1$ points $\mathcal{P}^n = \{P_0, P_1, ...P_n\}$. In the Euclidean space the dependence on the choice of the coordinate system and on $n+1$ points $\mathcal{P}^n$ determining this system, is fictitious. The geometrical object $\mathcal{T}_{Q\mathcal{P}^n}$ depends only on two points P_0, Q and coincides with the straight line $\mathcal{T}_{P_0Q}$. But at deformations of the Euclidean space the geometrical objects $\mathcal{T}_{Q\mathcal{P}^n}$ and $\mathcal{T}_{P_0Q}$ are deformed differently. The points $P_1, P_2, ...P_n$ cease to be fictitious in definition of $\mathcal{T}_{Q\mathcal{P}^n}$, and geometrical objects $\mathcal{T}_{Q\mathcal{P}^n}$ and $\mathcal{T}_{P_0Q}$ become to be different geometric objects, in general. But being different, in general, they may coincide in some special cases.

What of the two geometrical objects in the deformed geometry should be interpreted as the straight line, passing through the points P_0 and Q in the geometry $\mathcal{G}$? Of course, it is $\mathcal{T}_{P_0Q}$, because its definition does not contain a reference to a coordinate system, whereas definition of $\mathcal{T}_{Q\mathcal{P}^n}$ depends on the choice of the coordinate system, represented by points $\mathcal{P}^n$. In general, definitions of geometric objects and relations between them are not to refer to the means of description.

But in the given case the geometrical object $\mathcal{T}_{P_0Q}$ is, in general, $(n-1)$-dimensional surface, whereas $\mathcal{T}_{Q\mathcal{P}^n}$ is an intersection of $(n-1)$ $(n-1)$-dimensional surfaces, i.e. $\mathcal{T}_{Q\mathcal{P}^n}$ is, in general, a one-dimensional curve. The one-dimensional curve $\mathcal{T}_{Q\mathcal{P}^n}$ corresponds better to our ideas on the straight line, than the $(n-1)$-dimensional surface $\mathcal{T}_{P_0Q}$. Nevertheless, in physical geometry $\mathcal{G}$ it is $\mathcal{T}_{P_0Q}$, that is an analog of the Euclidean straight line.

It is very difficult to overcome our conventional idea that the Euclidean straight line cannot be deformed into many-dimensional surface, and *this idea has been prevent for years from construction of T-geometries.* Practically one uses such physical geometries, where deformation of the Euclidean space transforms the Euclidean straight lines into one-dimensional lines. It means that one chooses such geometries, where geometrical objects $\mathcal{T}_{P_0Q}$ and $\mathcal{T}_{Q\mathcal{P}^n}$ coincide.

$$\mathcal{T}_{P_0Q} = \mathcal{T}_{Q\mathcal{P}^n} \tag{2.16}$$

Condition (2.16) of coincidence of the objects $\mathcal{T}_{P_0Q}$ and $\mathcal{T}_{Q\mathcal{P}^n}$, imposed on the T-geometry, restricts list of possible T-geometries.

Let us consider the metric geometry, given on the set Ω of points. The metric space $M = \{\rho, \Omega\}$ is given by the metric (distance) ρ.

$$\begin{aligned}
\rho &: \quad \Omega \times \Omega \to [0, \infty) \subset \mathbf{R} && (2.17)\\
\rho(P,P) &= 0, \quad \rho(P,Q) = \rho(Q,P), \quad \forall P,Q \in \Omega && (2.18)\\
\rho(P,Q) &\geq 0, \quad \rho(P,Q) = 0, \quad \text{iff } P = Q, \quad \forall P,Q \in \Omega && (2.19)\\
0 &\leq \rho(P,R) + \rho(R,Q) - \rho(P,Q), \quad \forall P,Q,R \in \Omega && (2.20)
\end{aligned}$$

where $\mathbf{R}$ denotes the set of all real numbers. At first sight the metric space is a special case of the σ-space (2.1), and the metric geometry is a special case of the T-geometry with additional constraints (2.19), (2.20) imposed on the world function $\sigma = \frac{1}{2}\rho^2$. However it is not so, because the metric geometry does not use the deformation principle. The fact, that the Euclidean geometry can be described σ-immanently, as well as the conditions (2.3) - (2.10), were not known until 1990. Additional (with respect to the σ-space) constraints (2.19), (2.20) are imposed to eliminate the situation, when the straight line is not a one-dimensional line. The fact is that, in the metric geometry the shortest (straight) line can be constructed only in the case, when it is one-dimensional.

Let us consider the set $\mathcal{EL}(P,Q,a)$ of points R

$$\mathcal{EL}(P,Q,a) = \{R | f_{P,Q,a}(R) = 0\}, \qquad f_{P,Q,a}(R) = \rho(P,R) + \rho(R,Q) - 2a \tag{2.21}$$

If the metric space coincides with the proper Euclidean space, this set of points is an ellipsoid with focuses at the points P, Q and the large semiaxis a. The relations $f_{P,Q,a}(R) > 0$, $f_{P,Q,a}(R) = 0$, $f_{P,Q,a}(R) < 0$ determine respectively external points, boundary points and internal points of the ellipsoid. If $\rho(P,Q) = 2a$, we obtain the degenerate ellipsoid, which coincides with the segment $\mathcal{T}_{[PQ]}$ of the straight line, passing through the points P, Q. In the proper Euclidean geometry, the degenerate ellipsoid is one-dimensional segment of the straight line, but it is not evident that it is one-dimensional in the case of arbitrary metric geometry. For such a degenerate ellipsoid be one-dimensional in the arbitrary metric space, it is necessary that any degenerate ellipsoid $\mathcal{EL}(P,Q,\rho(P,Q)/2)$ have no internal points. This constraint is written in the form

$$f_{P,Q,\rho(P,Q)/2}(R) = \rho(P,R) + \rho(R,Q) - \rho(P,Q) \geq 0 \tag{2.22}$$

Comparing relation (2.22) with (2.20), we see that the constraint (2.20) is introduced to make the straight (shortest) line to be one-dimensional (absence of internal points in the geometrical object determined by two points).

As far as the metric geometry does not use the deformation principle, it is a poor geometry, because in the framework of this geometry one cannot construct the scalar product of two vectors, define linear independence of vectors and construct such geometrical objects as planes. All these objects as well as other are constructed on the basis of the deformation of the proper Euclidean geometry.

Generalizing the metric geometry, Menger [7] and Blumenthal [8] removed the triangle axiom (2.20). They tried to construct the distance geometry, which would be a more general geometry, than the metric one. As far as they did not use the deformation principle, they could not determine the shortest (straight) line without a reference to the topological concept of the curve $\mathcal{L}$, defined as a continuous mapping

$$\mathcal{L}: \qquad [0,1] \rightarrow \Omega \tag{2.23}$$

which cannot be expressed only via the distance. As a result the distance geometry appeared to be not a pure metric geometry, what the T-geometry is.

3 Conditions of the deformation principle application

Riemannian geometries satisfy the condition (2.16). The Riemannian geometry is a kind of inhomogeneous physical geometry, and, hence, it uses the deformation principle. Constructing the Riemannian geometry, the infinitesimal Euclidean distance is deformed into the Riemannian distance. The deformation is chosen in such a way that any Euclidean straight line $\mathcal{T}_{\mathrm{E}P_0Q}$, passing through the point P_0, collinear to the vector $\mathbf{P}_0\mathbf{Q}$, transforms into the geodesic $\mathcal{T}_{P_0Q}$, passing through the point P_0, collinear to the vector $\mathbf{P}_0\mathbf{Q}$ in the Riemannian space.

Note that in T-geometries, satisfying the condition (2.16) for all points $Q, \mathcal{P}^n$, the straight line

$$\mathcal{T}_{Q_0;P_0Q} = \{R \mid \mathbf{P}_0\mathbf{Q} || \mathbf{Q}_0\mathbf{R}\} \tag{3.1}$$

passing through the point Q_0 collinear to the vector $\mathbf{P}_0\mathbf{Q}$, is not a one-dimensional line, in general. If the Riemannian geometries be T-geometries, they would contain non-one-dimensional geodesics (straight lines). But the Riemannian geometries are not T-geometries, because at their construction one uses not only the deformation principle, but some other methods, containing a reference to the means of description. In particular, in the Riemannian geometries the absolute parallelism is absent, and one cannot to define a straight line (3.1), because the relation $\mathbf{P}_0\mathbf{Q} || \mathbf{Q}_0\mathbf{R}$ is not defined, if points P_0 and Q_0 do not coincide. On one hand, a lack of absolute parallelism allows one to go around the problem of non-one-dimensional straight lines. On the other hand, it makes the Riemannian geometries to be inconsistent, because they cease to be T-geometries, which are consistent by the construction (see for details [9]).

The fact is that the application of *only deformation principle* is sufficient for construction of a physical geometry. Besides, such a construction is consistent, because the original Euclidean geometry is consistent and, deforming it, we do not use any reasonings. If we introduce additional structure (for instance, a topological structure) we obtain a fortified physical geometry, i.e. a physical geometry with additional structure on it. The physical geometry with additional structure on it is a more pithy construction, than the physical geometry simply. But it is valid only in the case, when we consider the additional structure as an addition to the physical geometry. If we use an additional structure in construction of the geometry, we identify the additional structure with one of structures of the physical geometry. If we demand that the additional structure to be a structure of physical geometry, we restrict an application of the deformation principle and reduce the list of possible physical geometries, because coincidence of the additional structure with some structure of a physical geometry is possible not for all physical geometries, but only for some of them.

Let, for instance, we use concept of a curve $\mathcal{L}$ (2.23) for construction of a physical geometry. The concept of curve $\mathcal{L}$, considered as a continuous mapping is a topological structure, which cannot be expressed only via the distance or via the world function. A use of the mapping (2.23) needs an introduction of topological space and, in particular, the concept of continuity. If we identify the topological curve (2.23) with the "metrical" curve, defined as a broken line

$$\mathcal{T}_{\mathrm{br}} = \bigcup_i \mathcal{T}_{[P_iP_{i+1}]}, \qquad \mathcal{T}_{[P_iP_{i+1}]} = \left\{ R | \sqrt{2\sigma\left(P_i, P_{i+1}\right)} - \sqrt{2\sigma\left(P_i, R\right)} - \sqrt{2\sigma\left(R, P_{i+1}\right)} \right\} \tag{3.2}$$

consisting of the straight line segments $\mathcal{T}_{[P_iP_{i+1}]}$ between the points P_i, P_{i+1}, we truncate the list of possible geometries, because such an identification is possible only in some physical geometries. Identifying (2.23) and (3.2), we eliminate all discrete physical geometries and those continuous physical geometries, where the segment $\mathcal{T}_{[P_iP_{i+1}]}$ of straight line is a surface, but not a one-dimensional set of points. Thus, additional structures may lead to (i) a fortified physical geometry, (ii) a restricted physical geometry and (iii) a restricted fortified physical geometry. The result depends on the method of the additional structure application.

Note that some constraints (continuity, convexity, lack of absolute parallelism), imposed on physical geometries are a result of a disagreement of the applied means of the geometry construction. In the T-geometry, which uses only the deformation principle, there are no such restrictions. Besides, the T-geometry accepts some new property of a physical geometry, which is not accepted by conventional versions of physical geometry. This property, called the geometry nondegeneracy, follows directly from the application of arbitrary deformations to the proper Euclidean geometry.

The geometry is degenerate at the point P_0 in the direction of the vector $\mathbf{Q}_0\mathbf{Q}$, $|\mathbf{Q}_0\mathbf{Q}| \neq 0$, if the relations

$$\mathbf{Q}_0\mathbf{Q} \uparrow\uparrow \mathbf{P}_0\mathbf{R}: \qquad (\mathbf{Q}_0\mathbf{Q}.\mathbf{P}_0\mathbf{R}) = \sqrt{|\mathbf{Q}_0\mathbf{Q}| \cdot |\mathbf{P}_0\mathbf{R}|}, \qquad |\mathbf{P}_0\mathbf{R}| = a \neq 0 \tag{3.3}$$

considered as equations for determination of the point R, have not more, than one solution for any $a \neq 0$. Otherwise, the geometry is nondegenerate at the point P_0 in the direction of the vector $\mathbf{Q}_0\mathbf{Q}$. Note that the first equation (3.3) is the condition of the parallelism of vectors $\mathbf{Q}_0\mathbf{Q}$ and $\mathbf{P}_0\mathbf{R}$.

The proper Euclidean geometry is degenerate, i.e. it is degenerate at all points in directions of all vectors. Considering the Minkowski geometry, one should distinguish between the Minkowski T-geometry and Minkowski geometry. The two geometries are described by the same world function and differ in the definition of the parallelism. In the Minkowski T-geometry the parallelism of two vectors $\mathbf{Q_0Q}$ and $\mathbf{P_0R}$ is defined by the first equation (3.3). This definition is based on the deformation principle. In Minkowski geometry the parallelism is defined by the relation of the type of (2.13)

$$\mathbf{Q}_0\mathbf{Q}\uparrow\uparrow\mathbf{P}_0\mathbf{R}: \qquad (\mathbf{P}_0\mathbf{P}_i.\mathbf{Q}_0\mathbf{Q}) = a\,(\mathbf{P}_0\mathbf{P}_i.\mathbf{P}_0\mathbf{R}), \qquad i=1,2,...n, \qquad a>0 \tag{3.4}$$

where points $\mathcal{P}^n = \{P_0, P_1, ...P_n\}$ determine a rectilinear coordinate system with basic vectors $\mathbf{P}_0\mathbf{P}_i$, $i = 1, 2, ..n$ in the n-dimensional Minkowski geometry (n-dimensional pseudo-Euclidean geometry of index 1). Dependence of the definition (3.4) on the points $(P_1, P_2, ...P_n)$ is fictitious, but dependence on the number $n+1$ of points $\mathcal{P}^n$ is essential. Thus, definition (3.4) depends on the method of the geometry description.

The Minkowski T-geometry is degenerate at all points in direction of all timelike vectors, and it is nondegenerate at all points in direction of all spacelike vectors. The Minkowski geometry is degenerate at all points in direction of all vectors. Conventionally one uses the Minkowski geometry, ignoring the nondegeneracy in spacelike directions.

Considering the proper Riemannian geometry, one should distinguish between the Riemannian T-geometry and the Riemannian geometry. The two geometries are described by the same world function. They differ in the definition of the parallelism. In the Riemannian T-geometry the parallelism of two vectors $\mathbf{Q_0Q}$ and $\mathbf{P_0R}$ is defined by the first equation (3.3). In the Riemannian geometry the parallelism of two vectors $\mathbf{Q_0Q}$ and $\mathbf{P_0R}$ is defined only in the case, when the points P_0 and Q_0 coincide. Parallelism of remote vectors $\mathbf{Q_0Q}$ and $\mathbf{P_0R}$ is not defined, in general. This fact is known as absence of absolute parallelism.

The proper Riemannian T-geometry is locally degenerate, i.e. it is degenerate at all points P_0 in direction of vectors $\mathbf{P}_0\mathbf{Q}$. In the general case, when $P_0 \neq Q_0$, the proper Riemannian T-geometry is nondegenerate, in general. The proper Riemannian geometry is degenerate, because it is degenerate locally, whereas the nonlocal degeneracy is not defined in the Riemannian geometry, because of the lack of absolute parallelism. Conventionally one uses the Riemannian geometry (not Riemannian T-geometry) and ignores the property of the nondegeneracy completely.

From the viewpoint of the conventional approach to the physical geometry the nondegeneracy is an undesirable property of a physical geometry, although from the logical viewpoint and from viewpoint of the deformation principle the nondegeneracy is an inherent property of a physical geometry. The nonlocal nondegeneracy is ejected from the proper Riemannian geometry by denial of existence of the remote vector parallelism. Nondegeneracy in the spacelike directions is ejected from the Minkowski geometry by means of the redefinition of the two vectors parallelism. To appreciate this, let us consider an example.

4 Simple example of nondegenerate space-time geometry

The T-geometry [4] is defined on the σ-space $V = \{\sigma, \Omega\}$, where Ω is an arbitrary set of points and the world function σ is defined by the relations

$$\sigma: \qquad \Omega \times \Omega \rightarrow \mathbf{R}, \qquad \sigma(P,Q) = \sigma(Q,P), \qquad \sigma(P,P) = 0, \qquad \forall P, Q \in \Omega \tag{4.1}$$

where $\mathbf{R}$ denotes the set of all real numbers. Geometrical objects (vector $\mathbf{PQ}$, scalar product of vectors $(\mathbf{P}_0\mathbf{P}_1.\mathbf{Q}_0\mathbf{Q}_1)$, collinearity of vectors $\mathbf{P}_0\mathbf{P}_1 || \mathbf{Q}_0\mathbf{Q}_1$, segment of straight line $\mathcal{T}_{[P_0P_1]}$, etc.) are defined on the σ-space in the same way, as they are defined σ-immanently in the proper Euclidean space. Practically one uses the deformation principle, although it is not mentioned in all definitions.

Let us consider a simple example of the space-time geometry $\mathcal{G}_{\rm d}$, described by the T-geometry on 4-dimensional manifold $\mathcal{M}_{1+3}$. The world function $\sigma_{\rm d}$ is described by the relation

$$\sigma_{\rm d} = \sigma_{\rm M} + D(\sigma_{\rm M}) = \begin{cases} \sigma_{\rm M} + d & \text{if } \sigma_0 < \sigma_{\rm M} \\ \left(1 + \frac{d}{\sigma_0}\right)\sigma_{\rm M} & \text{if } 0 \leq \sigma_{\rm M} \leq \sigma_0 \\ \sigma_{\rm M} & \text{if } \sigma_{\rm M} < 0 \end{cases} \tag{4.2}$$

where $d \geq 0$ and $\sigma_0 > 0$ are some constants. The quantity $\sigma_{\rm M}$ is the world function in the Minkowski space-time geometry $\mathcal{G}_{\rm M}$. In the orthogonal rectilinear (inertial) coordinate system $x = (t, \mathbf{x})$ the world function $\sigma_{\rm M}$ has the form

$$\sigma_{\rm M}(x, x') = \frac{1}{2}\left(c^2(t-t')^2 - (\mathbf{x} - \mathbf{x}')^2\right) \tag{4.3}$$

where c is the speed of the light.

Let us compare the broken line (3.2) in Minkowski space-time geometry $\mathcal{G}_{\rm M}$ and in the distorted geometry $\mathcal{G}_{\rm d}$. We suppose that $\mathcal{T}_{\rm br}$ is timelike broken line, and all links $\mathcal{T}_{[P_iP_{i+1}]}$ of $\mathcal{T}_{\rm br}$ are timelike and have the same length

$$|\mathbf{P}_i\mathbf{P}_{i+1}|_{\rm d} = \sqrt{2\sigma_{\rm d}(P_i, P_{i+1})} = \mu_{\rm d} > 0, \qquad i = 0, \pm 1, \pm 2, ... \tag{4.4}$$

where indices "d" and "M" mean that the quantity is calculated by means of $\sigma_{\rm d}$ and $\sigma_{\rm M}$ respectively. Vector $\mathbf{P}_i\mathbf{P}_{i+1}$ is regarded as the momentum of the particle at the segment $\mathcal{T}_{[P_iP_{i+1}]}$, devided by the speed of the light c (we take for simplicity that $c = 1$). The quantity $|\mathbf{P}_i\mathbf{P}_{i+1}| = \mu$ is interpreted as its (geometric) mass. It follows from definition (2.5) and relation (4.2), that for timelike vectors $\mathbf{P}_i\mathbf{P}_{i+1}$ with $\mu > \sqrt{2\sigma_0}$

$$|\mathbf{P}_i\mathbf{P}_{i+1}|_{\rm d}^2 = \mu_{\rm d}^2 = \mu_{\rm M}^2 + 2d, \qquad \mu_{\rm M}^2 > 2\sigma_0 \tag{4.5}$$

$$\left(\mathbf{P}_{i-1}\mathbf{P}_i.\mathbf{P}_i\mathbf{P}_{i+1}\right)_{\mathrm{d}} = \left(\mathbf{P}_{i-1}\mathbf{P}_i.\mathbf{P}_i\mathbf{P}_{i+1}\right)_{\mathrm{M}} + d \tag{4.6}$$

Calculation of the shape of the segment $\mathcal{T}_{[P_0P_1]}\left(\sigma_{\mathrm{d}}\right)$ in $\mathcal{G}_{\mathrm{d}}$ gives the relation

$$r^2(\tau) = \begin{cases} \tau^2\mu_{\mathrm{d}}^2 \frac{\left(1-\frac{\tau d}{2(\sigma_0+d)}\right)^2}{\left(1-\frac{2d}{\mu_{\mathrm{d}}^2}\right)} - \frac{\tau^2\mu_{\mathrm{d}}^2\sigma_0}{(\sigma_0+d)}, & 0 < \tau < \frac{\sqrt{2(\sigma_0+d)}}{\mu_{\mathrm{d}}} \\ \frac{3d}{2} + 2d\left(\tau - 1/2\right)^2 \left(1 - \frac{2d}{\mu_{\mathrm{d}}^2}\right)^{-1}, & \frac{\sqrt{2(\sigma_0+d)}}{\mu_{\mathrm{d}}} < \tau < 1 - \frac{\sqrt{2(\sigma_0+d)}}{\mu_{\mathrm{d}}} \\ \left(1-\tau\right)^2 \mu_{\mathrm{d}}^2 \left[\frac{\left(1-\frac{(1-\tau)d}{2(\sigma_0+d)}\right)^2}{\left(1-\frac{2d}{\mu_{\mathrm{d}}^2}\right)} - \frac{\sigma_0}{(\sigma_0+d)}\right], & 1 - \frac{\sqrt{2(\sigma_0+d)}}{\mu_{\mathrm{d}}} < \tau < 1 \end{cases}, \tag{4.7}$$

where $r\left(\tau\right)$ is the spatial radius of the segment $\mathcal{T}_{[P_0P_1]}\left(\sigma_{\mathrm{d}}\right)$ in the coordinate system, where points P_0 and P_1 have coordinates $P_0 = \{0,0,0,0\}$, $P_1 = \{\mu_{\mathrm{d}},0,0,0\}$ and τ is a parameter along the segment $\mathcal{T}_{[P_0P_1]}\left(\sigma_{\mathrm{d}}\right)$ $\left(\tau\left(P_0\right) = 0,\ \tau\left(P_1\right) = 1\right)$. One can see from (4.7) that the characteristic value of the segment radius is $\sqrt{d}$.

Let the broken tube $\mathcal{T}_{\mathrm{br}}$ describe the "world line" of a free particle. It means by definition that any link $\mathbf{P}_{i-1}\mathbf{P}_i$ is parallel to the adjacent link $\mathbf{P}_i\mathbf{P}_{i+1}$

$$\mathbf{P}_{i-1}\mathbf{P}_i \uparrow\uparrow \mathbf{P}_i\mathbf{P}_{i+1}: \qquad \left(\mathbf{P}_{i-1}\mathbf{P}_i.\mathbf{P}_i\mathbf{P}_{i+1}\right) - \left|\mathbf{P}_{i-1}\mathbf{P}_i\right| \cdot \left|\mathbf{P}_i\mathbf{P}_{i+1}\right| = 0 \tag{4.8}$$

Definition of parallelism is different in geometries $\mathcal{G}_{\mathrm{M}}$ and $\mathcal{G}_{\mathrm{d}}$. As a result links, which are parallel in the geometry $\mathcal{G}_{\mathrm{M}}$, are not parallel in $\mathcal{G}_{\mathrm{d}}$ and vice versa.

Let $\mathcal{T}_{\mathrm{br}}\left(\sigma_{\mathrm{M}}\right)$ describe the world line of a free particle in the geometry $\mathcal{G}_{\mathrm{M}}$. The angle ϑ_{M} between the adjacent links in $\mathcal{G}_{\mathrm{M}}$ is defined by the relation

$$\cosh\vartheta_{\mathrm{M}} = \frac{\left(\mathbf{P}_{-1}\mathbf{P}_0.\mathbf{P}_0\mathbf{P}_1\right)_{\mathrm{M}}}{\left|\mathbf{P}_0\mathbf{P}_1\right|_{\mathrm{M}} \cdot \left|\mathbf{P}_{-1}\mathbf{P}_0\right|_{\mathrm{M}}} = 1 \tag{4.9}$$

The angle $\vartheta_{\mathrm{M}} = 0$, and the geometrical object $\mathcal{T}_{\mathrm{br}}\left(\sigma_{\mathrm{M}}\right)$ is a timelike straight line on the manifold $\mathcal{M}_{1+3}$.

Let now $\mathcal{T}_{\mathrm{br}}\left(\sigma_{\mathrm{d}}\right)$ describe the world line of a free particle in the geometry $\mathcal{G}_{\mathrm{d}}$. The angle ϑ_{d} between the adjacent links in $\mathcal{G}_{\mathrm{d}}$ is defined by the relation

$$\cosh\vartheta_{\mathrm{d}} = \frac{\left(\mathbf{P}_{i-1}\mathbf{P}_i.\mathbf{P}_i\mathbf{P}_{i+1}\right)_{\mathrm{d}}}{\left|\mathbf{P}_i\mathbf{P}_{i+1}\right|_{\mathrm{d}} \cdot \left|\mathbf{P}_{i-1}\mathbf{P}_i\right|_{\mathrm{d}}} = 1 \tag{4.10}$$

The angle $\vartheta_{\mathrm{d}} = 0$ also. If we draw the broken tube $\mathcal{T}_{\mathrm{br}}\left(\sigma_{\mathrm{d}}\right)$ on the manifold $\mathcal{M}_{1+3}$, using coordinates of basic points P_i and measure the angle ϑ_{dM} between the adjacent links in the Minkowski geometry $\mathcal{G}_{\mathrm{M}}$, we obtain for the angle ϑ_{dM} the following relation

$$\cosh\vartheta_{\mathrm{dM}} = \frac{\left(\mathbf{P}_{i-1}\mathbf{P}_i.\mathbf{P}_i\mathbf{P}_{i+1}\right)_{\mathrm{M}}}{\left|\mathbf{P}_i\mathbf{P}_{i+1}\right|_{\mathrm{M}} \cdot \left|\mathbf{P}_{i-1}\mathbf{P}_i\right|_{\mathrm{M}}} = \frac{\left(\mathbf{P}_{i-1}\mathbf{P}_i.\mathbf{P}_i\mathbf{P}_{i+1}\right)_{\mathrm{d}} - d}{\left|\mathbf{P}_i\mathbf{P}_{i+1}\right|_{\mathrm{d}}^2 - 2d} \tag{4.11}$$

Substituting the value of $(\mathbf{P}_{i-1}\mathbf{P}_i.\mathbf{P}_i\mathbf{P}_{i+1})_{\mathrm{d}}$, taken from (4.10), we obtain for the case, when $d \ll \mu_{\mathrm{d}}^2$

$$\cosh \vartheta_{\mathrm{dM}} = \frac{\mu_{\mathrm{d}}^d - d}{\mu_{\mathrm{d}}^2 - 2d} \approx 1 + \frac{d}{\mu_{\mathrm{d}}^2}, \qquad d \ll \mu_{\mathrm{d}}^2 \tag{4.12}$$

Hence, $\vartheta_{\mathrm{dM}} \approx \sqrt{2d}/\mu_{\mathrm{d}}$. It means, that the adjacent link is located on the cone of angle $\sqrt{2d}/\mu_{\mathrm{d}}$, and the whole line $\mathcal{T}_{\mathrm{br}}(\sigma_{\mathrm{d}})$ has a random shape, because any link wobbles with the characteristic angle $\sqrt{2d}/\mu_{\mathrm{d}}$. The wobble angle depends on the space-time distortion d and on the particle mass μ_{d}. The wobble angle is small for the large mass of a particle. The random displacement of the segment end is of the order $\mu_{\mathrm{d}}\vartheta_{\mathrm{dM}} = \sqrt{2d}$, i.e. of the same order as the segment width. It is reasonable, because these two phenomena have the common source: the space-time distortion D.

One should note that the space-time geometry influences the stochasticity of particle motion nonlocally in the sense, that the form of the world function (4.2) for values of $\sigma_{\mathrm{M}} < \frac{1}{2}\mu_{\mathrm{d}}^2$ is unessential for the motion stochasticity of the particle of the mass μ_{d}.

Such a situation, when the world line of a free particle is stochastic in the deterministic geometry, and this stochasticity depends on the particle mass, seems to be rather exotic and incredible. But experiments show that the motion of real particles of small mass is stochastic indeed, and this stochasticity increases, when the particle mass decreases. From physical viewpoint a theoretical foundation of the stochasticity is desirable, and some researchers invent stochastic geometries, noncommutative geometries and other exotic geometrical constructions, to obtain the quantum stochasticity. But in the Riemannian space-time geometry the particle motion does not depend on the particle mass, and in the framework of the Riemannian space-time geometry it is difficult to explain the quantum stochasticity by the space-time geometry properties. Distorted geometry $\mathcal{G}_{\mathrm{d}}$ explains the stochasticity and its dependence on the particle mass freely. Besides, at proper choice of the distortion d the statistical description of stochastic $\mathcal{T}_{\mathrm{br}}$ leads to the quantum description (Schrödinger equation) [10]. It is sufficient to set

$$d = \frac{\hbar}{2bc}, \tag{4.13}$$

where $\hbar$ is the quantum constant, c is the speed of the light, and b is some universal constant, connecting the geometrical mass μ with the usual particle mass m by means of the relation

$$m = b\mu \tag{4.14}$$

In other words, the distorted space-time geometry (4.2) is closer to the real space-time geometry, than the Minkowski geometry $\mathcal{G}_{\mathrm{M}}$.

5 Statistical description of stochastic world tubes

Statistical description of world lines cannot be a probabilistic statistical description, because the number of world lines may be negative. Indeed, the density of world lines in the vicinity of the space-time point x is defined by the relation

$$dN = j^k dS_k \tag{5.1}$$

where dN is the flux of world lines through the spacelike 3-area dS_k. The 4-vector $j^k = j^k(x)$ describes the world-lines density in the vicinity of the point x. The quantity dN may be interpreted as the number of world lines in the vicinity of the point x. This number may be negative.

In the nonrelativistic case the relation (5.1) turns into the relation

$$dN = j^0 dS_0 = \rho dV \tag{5.2}$$

where the particle density $j^0 = \rho \geq 0$, and ρ may be a ground for introduction of the probability density. In the relativistic case one cannot introduce the probability density, because the world line density is described by the 4-vector j^k.

For statistical description of stochastic world lines we use the dynamical conception of statistical description (DCSD), which does not use the concept of the probability [11].

Let $\mathcal{S}_{\mathrm{st}}$ be stochastic particle, whose state X is described by variables $\left\{\mathbf{x}, \frac{d\mathbf{x}}{dt}\right\}$, where $\mathbf{x}$ is the particle position. Evolution of the particle state is stochastic, and there exist no dynamic equations for $\mathcal{S}_{\mathrm{st}}$. Evolution of the state of $\mathcal{S}_{\mathrm{st}}$ contains both regular and stochastic components. To separate the regular evolution components, we consider a set (statistical ensemble) $\mathcal{E}\left[\mathcal{S}_{\mathrm{st}}\right]$ of many independent identical stochastic particles $\mathcal{S}_{\mathrm{st}}$. All stochastic particles $\mathcal{S}_{\mathrm{st}}$ start from the same initial state. It means that all $\mathcal{S}_{\mathrm{st}}$ are prepared in the same way. If the number N of $\mathcal{S}_{\mathrm{st}}$ is very large, the stochastic elements of evolution compensate each other, but regular ones are accumulated. In the limit $N \to \infty$ the statistical ensemble $\mathcal{E}\left[\mathcal{S}_{\mathrm{st}}\right]$ turns into a dynamic system, whose state evolves according to some dynamic equations.

Let the statistical ensemble $\mathcal{E}_{\mathrm{d}}\left[\mathcal{S}_{\mathrm{d}}\right]$ of deterministic classical particles $\mathcal{S}_{\mathrm{d}}$ be described by the action $\mathcal{A}_{\mathcal{E}_{\mathrm{d}}[\mathcal{S}_{\mathrm{d}}(P)]}$, where P are parameters describing $\mathcal{S}_{\mathrm{d}}$ (for instance, mass, charge). Let under influence of some stochastic agent the deterministic particle $\mathcal{S}_{\mathrm{d}}$ turn into a stochastic particle $\mathcal{S}_{\mathrm{st}}$. The action $\mathcal{A}_{\mathcal{E}_{\mathrm{st}}[\mathcal{S}_{\mathrm{st}}]}$ for the statistical ensemble $\mathcal{E}_{\mathrm{st}}\left[\mathcal{S}_{\mathrm{st}}\right]$ is reduced to the action $\mathcal{A}_{\mathcal{S}_{\mathrm{red}}[\mathcal{S}_{\mathrm{d}}]} = \mathcal{A}_{\mathcal{E}_{\mathrm{st}}[\mathcal{S}_{\mathrm{st}}]}$ for some set $\mathcal{S}_{\mathrm{red}}\left[\mathcal{S}_{\mathrm{d}}\right]$ of identical interacting deterministic particles $\mathcal{S}_{\mathrm{d}}$. The action $\mathcal{A}_{\mathcal{S}_{\mathrm{red}}[\mathcal{S}_{\mathrm{d}}]}$ as a functional of $\mathcal{S}_{\mathrm{d}}$ has the form $\mathcal{A}_{\mathcal{E}_{\mathrm{d}}[\mathcal{S}_{\mathrm{d}}(P_{\mathrm{eff}})]}$, where parameters P_{eff} are parameters P of the deterministic particle $\mathcal{S}_{\mathrm{d}}$, averaged over the statistical ensemble, and this averaging describes interaction of particles $\mathcal{S}_{\mathrm{d}}$ in the set $\mathcal{S}_{\mathrm{red}}\left[\mathcal{S}_{\mathrm{d}}\right]$. It means that

$$\mathcal{A}_{\mathcal{E}_{\mathrm{st}}[\mathcal{S}_{\mathrm{st}}]} = \mathcal{A}_{\mathcal{S}_{\mathrm{red}}[\mathcal{S}_{\mathrm{d}}(P)]} = \mathcal{A}_{\mathcal{E}_{\mathrm{d}}[\mathcal{S}_{\mathrm{d}}(P_{\mathrm{eff}})]} \tag{5.3}$$

In other words, stochasticity of particles $\mathcal{S}_{\mathrm{st}}$ in the ensemble $\mathcal{E}_{\mathrm{st}}\left[\mathcal{S}_{\mathrm{st}}\right]$ is replaced by interaction of $\mathcal{S}_{\mathrm{d}}$ in $\mathcal{S}_{\mathrm{red}}\left[\mathcal{S}_{\mathrm{d}}\right]$, and this interaction is described by a change

$$P \to P_{\mathrm{eff}} \tag{5.4}$$

in the action $\mathcal{A}_{\mathcal{E}_{\mathrm{d}}[\mathcal{S}_{\mathrm{d}}(P)]}$.

The free particle has the unique parameter - its mass m, and the action $\mathcal{A}_{\mathcal{S}_{\mathrm{d}}}$ for the free deterministic particle has the form

$$\mathcal{S}_{\mathrm{d}}: \qquad \mathcal{A}_{\mathcal{S}_{\mathrm{d}}}[\mathbf{x}] = \int \frac{m}{2}\left(\frac{d\mathbf{x}}{dt}\right)^2 dt \tag{5.5}$$

where $\mathbf{x} = \mathbf{x}(t) = \{x^1(t), x^2(t), x^3(t)\}$, and the time t is the independent variable.

The action $\mathcal{A}_{\mathcal{E}_{\mathrm{d}}[\mathcal{S}_{\mathrm{d}}(P)]}$ for the pure statistical ensemble $\mathcal{E}_{\mathrm{d}}[\mathcal{S}_{\mathrm{d}}]$ of free deterministic particles $\mathcal{S}_{\mathrm{d}}$ has the form

$$\mathcal{E}_{\mathrm{d}}[\mathcal{S}_{\mathrm{d}}]: \qquad \mathcal{A}_{\mathcal{E}_{\mathrm{d}}[\mathcal{S}_{\mathrm{d}}]}[\mathbf{x}] = \int \frac{m}{2}\left(\frac{d\mathbf{x}}{dt}\right)^2 dt d\boldsymbol{\xi} \tag{5.6}$$

where $\mathbf{x} = \mathbf{x}(t,\boldsymbol{\xi}) = \{x^1(t,\boldsymbol{\xi}), x^2(t,\boldsymbol{\xi}), x^3(t,\boldsymbol{\xi})\}$. Independent variables $\boldsymbol{\xi} = \{\xi_1, \xi_2, \xi_3\}$ label elements $\mathcal{S}_{\mathrm{d}}$ of the statistical ensemble $\mathcal{E}_{\mathrm{d}}[\mathcal{S}_{\mathrm{d}}]$. The variables $\boldsymbol{\xi}$ are known as Lagrangian coordinates. Statistical ensemble $\mathcal{E}_{\mathrm{d}}[\mathcal{S}_{\mathrm{d}}]$ is a continuous dynamic system, having infinite number of the freedom degrees, whereas the particle $\mathcal{S}_{\mathrm{d}}$ is the discrete dynamic system having six degrees of freedom.

If the particles are stochastic, the action $\mathcal{A}_{\mathcal{E}_{\mathrm{st}}[\mathcal{S}_{\mathrm{st}}]}$ for the pure statistical ensemble $\mathcal{E}_{\mathrm{st}}[\mathcal{S}_{\mathrm{st}}]$ of free quantum stochastic particles $\mathcal{S}_{\mathrm{st}}$ has the form

$$\mathcal{E}_{\mathrm{st}}[\mathcal{S}_{\mathrm{st}}]: \qquad \mathcal{A}_{\mathcal{E}_{\mathrm{st}}[\mathcal{S}_{\mathrm{st}}]}[\mathbf{x},\mathbf{u}] = \int \left\{\frac{m}{2}\left(\frac{d\mathbf{x}}{dt}\right)^2 + \frac{m}{2}\mathbf{u}^2 - \frac{\hbar}{2}\boldsymbol{\nabla}\mathbf{u}\right\} dt d\boldsymbol{\xi} \tag{5.7}$$

where $\mathbf{u} = \mathbf{u}(t,\mathbf{x})$ is a vector function of arguments $t,\mathbf{x}$ (not of $t,\boldsymbol{\xi}$), and $\mathbf{x} = \mathbf{x}(t,\boldsymbol{\xi})$ is a vector function of independent variables $t,\boldsymbol{\xi}$. The 3-vector $\mathbf{u}$ describes the mean value of the stochastic component of the particle motion, which is a function of the variables $t,\mathbf{x}$. The first term $\frac{m}{2}\left(\frac{d\mathbf{x}}{dt}\right)^2$ describes the energy of the regular component of the stochastic particle motion. The second term $m\mathbf{u}^2/2$ describes the energy of the random component of velocity. The components $\frac{d\mathbf{x}}{dt}$ and $\mathbf{u}$ of the total velocity are connected with different degrees of freedom, and their energies should be added in the expression for the Lagrange function density. The last term $-\hbar\boldsymbol{\nabla}\mathbf{u}/2$ describes interaction between the regular component $\frac{d\mathbf{x}}{dt}$ and the random one $\mathbf{u}$. Note that $m\mathbf{u}^2/2$ is a function of $t,\mathbf{x}$. It influences on the regular component $\frac{d\mathbf{x}}{dt}$ as a potential energy $U(t,\mathbf{x},\nabla\mathbf{x}) = -m\mathbf{u}^2/2$, generated by the random component.

The dynamic system (5.7) is a statistical ensemble, because the Lagrange function density of the action (5.7) does not depend on $\boldsymbol{\xi}$ explicitly, and we can represent the action for the single system $\mathcal{S}_{\mathrm{st}}$

$$\mathcal{S}_{\mathrm{st}}: \qquad \mathcal{A}_{\mathcal{S}_{\mathrm{st}}}[\mathbf{x},\mathbf{u}] = \int \left\{\frac{m}{2}\left(\frac{d\mathbf{x}}{dt}\right)^2 + \frac{m}{2}\mathbf{u}^2 - \frac{\hbar}{2}\boldsymbol{\nabla}\mathbf{u}\right\} dt \tag{5.8}$$

Unfortunately, the expression for the action (5.8) is only symbolic, because the differential operator $\boldsymbol{\nabla} = \{\partial/\partial x^\alpha\}$, $\alpha = 1,2,3$ is defined in the continuous vicinity of the point $\mathbf{x}$, but not only for one point $\mathbf{x}$. The expression (5.8) ceases to be symbolic, only if $\hbar = 0$. In this case the last term, containing $\mathbf{\nabla}$ vanishes. Variation of (5.8) with respect to $\mathbf{u}$ gives $\mathbf{u} = 0$, and the action (5.8) coincides with the action (5.6) for $\mathcal{S}_{\mathrm{d}}$. If $\hbar \neq 0$, the expression for the action (5.8) is not the well defined, and dynamic equations for $\mathcal{S}_{\mathrm{st}}$ are absent.

Dynamic equation for $\mathbf{u}$ is obtained from the action functional (5.7) by means of variation with respect to $\mathbf{u}$. If the quantum constant $\hbar = 0$, it follows from the dynamic equation for $\mathbf{u}$, that $\mathbf{u} = 0$, and the action (5.7) reduces to the form (5.6). In the general case $\hbar \neq 0$ we are to go to independent variables $\mathbf{x},$ because $\mathbf{u}$ is a function of $t, \mathbf{x}$. We obtain instead of (5.7)

$$\mathcal{E}_{\mathrm{st}}\left[\mathcal{S}_{\mathrm{st}}\right]: \qquad \mathcal{A}_{\mathcal{E}_{\mathrm{st}}\left[\mathcal{S}_{\mathrm{st}}\right]}\left[\mathbf{x},\mathbf{u}\right] = \int \left\{ \frac{m}{2}\left(\frac{d\mathbf{x}}{dt}\right)^{2} + \frac{m}{2}\mathbf{u}^{2} - \frac{\hbar}{2}\mathbf{\nabla}\mathbf{u} \right\} \rho dt d\mathbf{x} \tag{5.9}$$

$$\rho = \frac{\partial\left(\xi_{1},\xi_{2},\xi_{3}\right)}{\partial\left(x^{1},x^{2},x^{3}\right)} = \left(\frac{\partial\left(x^{1},x^{2},x^{3}\right)}{\partial\left(\xi_{1},\xi_{2},\xi_{3}\right)}\right)^{-1} \tag{5.10}$$

Variation of (5.10) with respect to $\mathbf{u}$ gives

$$\frac{\delta\mathcal{A}_{\mathcal{E}_{\mathrm{st}}\left[\mathcal{S}_{\mathrm{st}}\right]}}{\delta\mathbf{u}} = m\rho\mathbf{u} + \frac{\hbar}{2}\mathbf{\nabla}\rho = 0 \tag{5.11}$$

Resolving dynamic equation (5.11) with respect to $\mathbf{u}$ in the form

$$\mathbf{u} = -\frac{\hbar}{2m}\mathbf{\nabla}\ln\rho \tag{5.12}$$

we can eliminate the mean stochastic velocity $\mathbf{u}$ from the action (5.9). We obtain instead of (5.9)

$$\mathcal{E}_{\mathrm{st}}\left[\mathcal{S}_{\mathrm{st}}\right]: \qquad \mathcal{A}_{\mathcal{E}_{\mathrm{st}}\left[\mathcal{S}_{\mathrm{st}}\right]}\left[\mathbf{x}\right] = \int \left\{ \frac{m}{2}\left(\frac{d\mathbf{x}}{dt}\right)^{2} - U\left(\rho,\mathbf{\nabla}\rho\right) \right\} \rho dt d\mathbf{x} \tag{5.13}$$

where

$$\rho U\left(\rho,\mathbf{\nabla}\rho\right) = -\frac{\hbar^{2}}{8m}\frac{\left(\mathbf{\nabla}\rho\right)^{2}}{\rho} - \frac{\hbar^{2}}{4m}\rho\mathbf{\nabla}^{2}\ln\rho \tag{5.14}$$

and ρ is defined by (5.10). Eliminating divergence, we obtain instead of (5.14)

$$U\left(\rho,\mathbf{\nabla}\rho\right) = \frac{\hbar^{2}}{8m}\frac{\left(\mathbf{\nabla}\rho\right)^{2}}{\rho^{2}} + \frac{\hbar^{2}}{4m}\frac{1}{\rho}\mathbf{\nabla}^{2}\rho \tag{5.15}$$

The last term in (5.15) does not give a contribution into dynamic equations, and it may be omitted. The action (5.13) turns into

$$\mathcal{E}_{\mathrm{st}}\left[\mathcal{S}_{\mathrm{st}}\right]: \qquad \mathcal{A}_{\mathcal{E}_{\mathrm{st}}\left[\mathcal{S}_{\mathrm{st}}\right]}\left[\boldsymbol{\xi}\right] = \int \left\{ \frac{m}{2}\left(\frac{d\mathbf{x}}{dt}\right)^{2} - \frac{\hbar^{2}}{8m}\frac{\left(\mathbf{\nabla}\rho\right)^{2}}{\rho^{2}} \right\} \rho dt d\mathbf{x} \tag{5.16}$$

where variables $t, \mathbf{x}$ are independent variables, and variables $\boldsymbol{\xi}$ are considered to be dependent variables. The quantities ρ and $\frac{d\mathbf{x}}{dt}$ are functions of the dependent variables $\boldsymbol{\xi}$ derivatives with respect to t and $\mathbf{x}$

$$\rho = \frac{\partial \left(\xi_1, \xi_2, \xi_3\right)}{\partial \left(x^1, x^2, x^3\right)} \tag{5.17}$$

$$\frac{dx^\alpha}{dt} = \frac{\partial \left(x^\alpha, \xi_1, \xi_2, \xi_3\right)}{\partial \left(t, \xi_1, \xi_2, \xi_3\right)} = \rho^{-1} \frac{\partial \left(x^\alpha, \xi_1, \xi_2, \xi_3\right)}{\partial \left(t, x^1, x^2, x^3\right)}, \qquad \alpha = 1, 2, 3 \tag{5.18}$$

Dynamic equations, generated by the action (5.16), are rather complicated. However, in terms of the wave function the action (5.16) takes a more simple form [12].

In terms of the two-component wave function ψ

$$\psi = \{\psi_1, \psi_2\}, \qquad \psi^* = \left\{ \begin{array}{c} \psi_1^* \\ \psi_2^* \end{array} \right\}, \qquad \rho \equiv \psi^* \psi \equiv \psi_1^* \psi_1 + \psi_2^* \psi_2, \tag{5.19}$$

the action (5.18) takes the form

$$\begin{aligned} \mathcal{E}_{\text{st}}\left[\mathcal{S}_{\text{st}}\right] \quad : \qquad \mathcal{A}_{\mathcal{E}_{\text{st}}[\mathcal{S}_{\text{st}}]}\left[\psi, \psi^*\right] = \int \Bigg\{ & \frac{ib_0}{2}\left(\psi^* \partial_0 \psi - \partial_0 \psi^* \cdot \psi\right) - \frac{b_0^2}{2m} \boldsymbol{\nabla} \psi^* \boldsymbol{\nabla} \psi \\ & + \frac{b_0^2}{8m} \sum_{\alpha=1}^{\alpha=3} (\boldsymbol{\nabla} s_\alpha)^2 \rho + \frac{b_0^2 - \hbar^2}{8\rho m} (\boldsymbol{\nabla} \rho)^2 \Bigg\} dt d\mathbf{x}, \end{aligned} \tag{5.20}$$

where

$$s_\alpha \equiv \frac{\psi^* \sigma_\alpha \psi}{\rho}, \qquad \alpha = 1, 2, 3, \tag{5.21}$$

and σ_α are the Pauli matrices

$$\sigma_1 = \left(\begin{array}{cc} 0 & 1 \\ 1 & 0 \end{array} \right), \qquad \sigma_2 = \left(\begin{array}{cc} 0 & -i \\ i & 0 \end{array} \right), \qquad \sigma_3 = \left(\begin{array}{cc} 1 & 0 \\ 0 & -1 \end{array} \right) \tag{5.22}$$

Here the constant b_0 is an arbitrary constant. We transit from the action (5.16) to the action (5.20) by means of the change of variables, accompanied by the integration of dynamic equations and by the appearance of three arbitrary functions $\mathbf{g}\left(\boldsymbol{\xi}\right) = \left\{g^1\left(\boldsymbol{\xi}\right), g^2\left(\boldsymbol{\xi}\right), g^3\left(\boldsymbol{\xi}\right)\right\}$.

The change of variables, connecting dependent variables $\boldsymbol{\xi}$ and ψ, has the form (see Appendix A or [12])

$$\psi_\alpha = \sqrt{\rho} e^{i\varphi} u_\alpha(\boldsymbol{\xi}), \qquad \psi_\alpha^* = \sqrt{\rho} e^{-i\varphi} u_\alpha^*(\boldsymbol{\xi}), \qquad \alpha = 1, 2, \ldots, n, \tag{5.23}$$

$$\psi^* \psi \equiv \sum_{\alpha=1}^{n} \psi_\alpha^* \psi_\alpha, \tag{5.24}$$

where (*) means the complex conjugate. The quantities $u_\alpha(\boldsymbol{\xi})$, $\alpha = 1, 2, ...n$ are functions of only variables $\boldsymbol{\xi}$, and satisfy the relations

$$-\frac{i}{2} \sum_{\alpha=1}^{n} \left(u_\alpha^* \frac{\partial u_\alpha}{\partial \xi_\beta} - \frac{\partial u_\alpha^*}{\partial \xi_\beta} u_\alpha \right) = g^\beta(\boldsymbol{\xi}), \qquad \beta = 1, 2, 3, \qquad \sum_{\alpha=1}^{n} u_\alpha^* u_\alpha = 1. \tag{5.25}$$

Here φ is the new dependent variable, appearing from the fictitious temporal Lagrangian coordinate ξ_0, and b_0 is an arbitrary constant. The number n is such a natural number that equations (5.25) admit a solution. In general, n depends on the form of the arbitrary integration functions $\mathbf{g} = \{g^\beta(\boldsymbol{\xi})\}$, $\beta = 1, 2, 3$.

The meaning of the wave function ψ is not clear, and interpretation is produced on the basis of the action (5.9) or (5.16), where meaning of all quantities is quite clear. The action (5.9) describes the flow of some fluid with the density ρ, determined by the relation (5.10), and the flux density

$$\mathbf{j} = \rho \frac{d\mathbf{x}}{dt} \tag{5.26}$$

In terms of the wave function ψ these quantities have the form

$$\rho = \psi^* \psi, \qquad \mathbf{j} = -\frac{ib_0}{2m} \left(\psi^* \boldsymbol{\nabla} \psi - \boldsymbol{\nabla} \psi^* \cdot \psi \right) \tag{5.27}$$

The functions $\mathbf{g}$ determine vorticity of the fluid flow. If $\mathbf{g} = 0$, equations (5.25) have the solution $u_1 = 1$, $u_\alpha = 0$, $\alpha = 2, 3, ...n$. In this case the function ψ may have one component (other components vanish), and the fluid flow is irrotational. The function ψ has the form

$$\psi = \sqrt{\rho} e^{i\varphi}, \qquad \psi^* = \sqrt{\rho} e^{-i\varphi} \tag{5.28}$$

and the fluid velocity

$$\mathbf{v} = \frac{\mathbf{j}}{\rho} = \boldsymbol{\nabla} \frac{b_0 \varphi}{m} \tag{5.29}$$

has the potential $b_0 \varphi / m$.

In the partial case of the irrotational fluid flow

$$s_\alpha \equiv \frac{\psi^* \sigma_\alpha \psi}{\rho} = \text{const}, \qquad \alpha = 1, 2, 3 \tag{5.30}$$

and the action (5.20) turns into the action

$$\mathcal{A}_{\mathcal{S}_\mathrm{q}} \left[\psi, \psi^* \right] = \int \left\{ \frac{ib_0}{2} \left(\psi^* \partial_0 \psi - \partial_0 \psi^* \cdot \psi \right) - \frac{b_0^2}{2m} \boldsymbol{\nabla} \psi^* \boldsymbol{\nabla} \psi + \frac{b_0^2 - \hbar^2}{8\rho m} \left(\boldsymbol{\nabla} \rho \right)^2 \right\} dt d\mathbf{x}, \tag{5.31}$$

If we choose the arbitrary constant b_0 in the form $b_0 = \hbar$, the action (5.31) turns into the action

$$\mathcal{A}_{\mathcal{S}_\mathrm{q}} \left[\psi, \psi^* \right] = \int \left\{ \frac{i\hbar}{2} \left(\psi^* \partial_0 \psi - \partial_0 \psi^* \cdot \psi \right) - \frac{\hbar^2}{2m} \boldsymbol{\nabla} \psi^* \boldsymbol{\nabla} \psi \right\} dt d\mathbf{x}, \tag{5.32}$$

having the Schrödinger equation

$$i\hbar \partial_0 \psi = -\frac{\hbar^2}{2m} \boldsymbol{\nabla}^2 \psi \tag{5.33}$$

as the dynamic equation. Expressions (5.27) for the density and the particle flux turn into the conventional expressions

$$\rho=\psi^*\psi,\qquad \mathbf{j}=-\frac{i\hbar}{2m}\left(\psi^*\boldsymbol{\nabla}\psi-\boldsymbol{\nabla}\psi^*\cdot\psi\right) \tag{5.34}$$

Interpretation of all quantities is obtained on the basis the fact, that the quantum description in terms of the Schrödinger equation is the special case of the statistical description in terms of the statistical ensemble (5.7).

Can we obtain the statistical ensemble (5.7) from the statistical ensemble (5.6) by means of the change $m\rightarrow m_{\text{eff}}$? It is possible, if we represent the nonrelativistic action (5.6) as the nonrelativistic approximation

$$\mathcal{E}_{\text{d}}\left[\mathcal{S}_{\text{d}}\right]:\qquad \mathcal{A}_{\mathcal{E}_{\text{d}}\left[\mathcal{S}_{\text{d}}\right]}\left[\mathbf{x}\right]=\int\left\{-mc^2+\frac{m}{2}\left(\frac{d\mathbf{x}}{dt}\right)^2\right\}dtd\boldsymbol{\xi} \tag{5.35}$$

of the relativistic action

$$\mathcal{E}_{\text{d}}\left[\mathcal{S}_{\text{d}}\right]:\qquad \mathcal{A}_{\mathcal{E}_{\text{d}}\left[\mathcal{S}_{\text{d}}\right]}\left[\mathbf{x}\right]=-\int mc^2\sqrt{1-\frac{1}{c^2}\left(\frac{d\mathbf{x}}{dt}\right)^2}dtd\boldsymbol{\xi} \tag{5.36}$$

The action (5.7) is obtained from the action (5.35) as a result of the change

$$m\rightarrow m_{\text{eff}}=m\left(1-\frac{\mathbf{u}^2}{2c^2}+\frac{\hbar}{2mc^2}\boldsymbol{\nabla}\mathbf{u}\right) \tag{5.37}$$

Practically, the change is produced only in the first term of the action (5.35), because the change in the second term gives additional term of the order of c^{-2}, which is small in the nonrelativistic approximation. Another version of the change in the action (5.35) has the form

$$m\rightarrow m_{\text{eff}}=m\left(1-\frac{\hbar^2}{8m^2c^2}\frac{\left(\boldsymbol{\nabla}\rho\right)^2}{\rho^2}-\frac{\hbar^2}{4m^2c^2}\frac{1}{\rho}\boldsymbol{\nabla}^2\rho\right) \tag{5.38}$$

or

$$m\rightarrow m_{\text{eff}}=m\left(1+\frac{\hbar^2}{8m^2c^2}\frac{\left(\boldsymbol{\nabla}\rho\right)^2}{\rho^2}\right) \tag{5.39}$$

The relation (5.38) is obtained from (5.37) after substitution of (5.12). Producing the change (5.39) in the action (5.35), we obtain in the nonrelativistic approximation the action (5.16).

In the relativistic case instead of the change (5.37) we have

$$m^2\rightarrow m_{\text{eff}}^2=m^2\left(1+u_lu^l+\lambda\partial_lu^l\right),\qquad \lambda=\frac{\hbar}{mc} \tag{5.40}$$

where the variables $u^k=u^k\left(x\right)=u^k\left(t,\mathbf{x}\right)$, $k=0,1,2,3$ are new dependent variables, describing the mean value of the stochastic component of the particle 4-velocity.

The change (5.40) in the action (5.36) for the statistical ensemble of free relativistic particles leads finally to the action [13]

$$\mathcal{A}\left[\psi,\psi^{*}\right]=\int\left\{\hbar^{2}\partial_{k}\psi^{*}\partial^{k}\psi-m^{2}c^{2}\rho-\frac{\hbar^{2}}{4}\left(\partial_{l}s_{\alpha}\right)\left(\partial^{l}s_{\alpha}\right)\rho\right\}d^{4}x \tag{5.41}$$

where ψ is the two-component wave function (5.23) - (5.25). The variables ρ, s_α are defined by the relation (5.27) and, besides, the constant $b_0=\hbar$. The action (5.41) is the action for the statistical ensemble of free stochastic relativistic particles. In the case of irrotational flow, when the wave function ψ may be one-component, s_α =const, and the dynamic equation for the action (5.41) is the Klein-Gordon equation.

$$\hbar^{2}\partial_{k}\partial^{k}\psi+m^{2}c^{2}\psi=0 \tag{5.42}$$

6 Determination of the effective mass

We are going to show, that the change (5.39) follows from the form of the world function (4.2). In reality in [10] the inverse problem has been solved. What is the geometry of the uniform space-time, if the statistical description of free nonrelativistic particles leads to the quantum description in terms of the Schrödinger equation? Having solved this problem, we obtained the world function (4.2). Now we show that the effective mass m_{eff} of the nonrelativistic particle is determined by the relation (5.39).

Mathematical formalism of theoretical physics is suited for application in the Minkowski space-time. Mathematical formalism for work in the distorted space-time V_{d} with the world function (4.2) is absent now. We are forced to work in the Minkowski space-time, using conventional technique and taking into account distortion of the space-time by means of some corrections.

Let introduce the notion of the adduced vector $\vec{p}=\vec{p}\left(a,P_0,P_1\right)$ as a totality of a real or imaginary number a and two points $\{P_0,P_1\}$

$$\vec{p}=\vec{p}\left(a,P_0,P_1\right)=a\left(\mathbf{P}_0\mathbf{P}_1\right)=a\mathbf{P}_0\mathbf{P}_1 \tag{6.1}$$

The number a is called the gauge of the adduced vector. The vector $\mathbf{P}_0\mathbf{P}_1$ is a partial case of the adduced vector $a\mathbf{P}_0\mathbf{P}_1$ with the gauge $a=1$. The scalar product of two adduced vectors $a_1\mathbf{P}_0\mathbf{P}_1$ and $a_2\mathbf{Q}_0\mathbf{Q}_1$ is defined by the relation

$$\left(a_1\mathbf{P}_0\mathbf{P}_1.a_2\mathbf{Q}_0\mathbf{Q}_1\right)=a_1a_2\left(\mathbf{P}_0\mathbf{P}_1.\mathbf{Q}_0\mathbf{Q}_1\right) \tag{6.2}$$

We shall consider statistical ensemble of relativistic particles, described by the action (5.36) with the oriented mass m_{o}, defined by the relation

$$m_{\text{o}}=b\mu_{\text{o}},\qquad \mu_{\text{o}}=\left(\mathbf{P}_0\mathbf{P}_1.\vec{u}\left(R\right)\right) \tag{6.3}$$

where $\vec{u}=\vec{u}\left(R\right)$ is the unit adduced vector of the 4-velocity at the point $R\in\mathcal{T}_{[P_0P_1]}$, $\mathbf{P}_0\mathbf{P}_1$ is the momentum vector, divided by the speed of the light c. The quantity

m_{o} is called the oriented mass because it depends on the mutual orientation of the momentum vector and of the 4-velocity. The oriented mass m_{o} has different sign for the particle and for the antiparticle.

The 4-velocity $\vec{u} = \vec{u}(R)$ is the unit adduced vector inside the segment $\mathcal{T}_{[P_0 P_1]}$ in the space-time V_{d}

$$\vec{u}(R) = |\mathbf{P}_0\mathbf{R}|_{\mathrm{d}}^{-1} \mathbf{P}_0\mathbf{R} = (\mathbf{P}_0\mathbf{R}.\mathbf{P}_0\mathbf{R})_{\mathrm{d}}^{-1/2} \mathbf{P}_0\mathbf{R}, \qquad R \in \mathcal{T}_{[P_0 P_1]} \tag{6.4}$$

$$(\vec{u}(R).\vec{u}(R))_{\mathrm{d}} = 1 \tag{6.5}$$

The particle mass, defined by the relation (6.3), is different in V_{d} and in V_{M}. As far as $R \in \mathcal{T}_{[P_0 P_1]}$ and, hence, $\mathbf{P}_0\mathbf{R} \uparrow\uparrow_{\mathrm{d}} \mathbf{P}_0\mathbf{P}_1$.

$$(\mathbf{P}_0\mathbf{P}_1.\mathbf{P}_0\mathbf{R})_{\mathrm{d}} = |\mathbf{P}_0\mathbf{P}_1|_{\mathrm{d}} \cdot |\mathbf{P}_0\mathbf{R}|_{\mathrm{d}}, \tag{6.6}$$

we obtain for m_{od}

$$\begin{aligned} m_{\mathrm{od}} &= b(\mathbf{P}_0\mathbf{P}_1.\vec{u}(R))_{\mathrm{d}} = b|\mathbf{P}_0\mathbf{R}|_{\mathrm{d}}^{-1} (\mathbf{P}_0\mathbf{P}_1.\mathbf{P}_0\mathbf{R})_{\mathrm{d}} \\ &= b|\mathbf{P}_0\mathbf{R}|_{\mathrm{d}}^{-1} \cdot |\mathbf{P}_0\mathbf{P}_1|_{\mathrm{d}} \cdot |\mathbf{P}_0\mathbf{R}|_{\mathrm{d}} = b|\mathbf{P}_0\mathbf{P}_1|_{\mathrm{d}} = b\mu_{\mathrm{d}} \end{aligned} \tag{6.7}$$

where b is the constant, defined by (4.14).

If the point R on the segment $\mathcal{T}_{[P_0 P_1]}$ is not close to the ends P_0 and P_1, (i.e. $|\mathbf{P}_0\mathbf{R}|_{\mathrm{d}}^2 > 2\sigma_0$, $|\mathbf{P}_0\mathbf{P}_1|_{\mathrm{d}}^2 > 2\sigma_0$) and relation (4.6) is satisfied, we obtain for the oriented mass m_{oM} in V_{M}

$$\begin{aligned} m_{\mathrm{oM}} &= b(\mathbf{P}_0\mathbf{P}_1.\vec{u}(R))_{\mathrm{M}} = b|\mathbf{P}_0\mathbf{R}|_{\mathrm{d}}^{-1} (\mathbf{P}_0\mathbf{P}_1.\mathbf{P}_0\mathbf{R})_{\mathrm{M}} \\ &= b|\mathbf{P}_0\mathbf{R}|_{\mathrm{d}}^{-1} ((\mathbf{P}_0\mathbf{P}_1.\mathbf{P}_0\mathbf{R})_{\mathrm{d}} - 2d) \\ &= b|\mathbf{P}_0\mathbf{P}_1|_{\mathrm{d}} - 2db|\mathbf{P}_0\mathbf{R}|_{\mathrm{d}}^{-1} = b\mu_{\mathrm{d}} - \frac{2bd}{|\mathbf{P}_0\mathbf{R}|_{\mathrm{d}}} \end{aligned} \tag{6.8}$$

Thus, the particle mass m_{oM}, defined by the relation (6.3) and calculated in V_{M} depends on the point R on the surface of the segment $\mathcal{T}_{[P_0 P_1]}$. We use in the action (5.36) some effective mass m_{eff}, calculated in accordance with (6.8) in the Minkowski space-time V_{M} by means of the relation

$$m_{\mathrm{eff}} = b(\mathbf{P}_0\mathbf{P}_1.\vec{u}_{\mathrm{eff}})_{\mathrm{M}} \tag{6.9}$$

where the adduced vector $\vec{u}_{\mathrm{eff}}$ is the mean 4-velocity inside the segment $\mathcal{T}_{[P_0 P_1]}$.

Let the point P be the center of the segment $\mathcal{T}_{[P_0 P_1]}$, as it shown in figure 1. The points P' and P'' are centers of segments $\mathcal{T}_{[P_0' P_1']}$, $\mathcal{T}_{[P_0'' P_1'']}$, of adjacent world tubes of the statistical ensemble. We consider nonrelativistic case, and the vectors $\mathbf{P}_0\mathbf{P}_1$, $\mathbf{P}_0'\mathbf{P}_1'$, $\mathbf{P}_0''\mathbf{P}_1''$ may be considered to be parallel in V_{M}. Let segments $\mathcal{T}_{[P_0 P_1]}$, $\mathcal{T}_{[P_0' P_1']}$, $\mathcal{T}_{[P_0'' P_1'']}$ be placed in such a way, that $P \in \mathcal{T}_{[P_0' P_1']}$, $P \in \mathcal{T}_{[P_0'' P_1'']}$. The 4-velocity of the segment $\mathcal{T}_{[P_0' P_1']}$, determined by the vector $\mathbf{P}_0'\mathbf{P}$, and the 4-velocity of the segment $\mathcal{T}_{[P_0'' P_1'']}$, determined by the vector $\mathbf{P}_0''\mathbf{P}$, make a contribution in the effective 4-velocity $\vec{u}_{\text{eff}}$ of the segment $\mathcal{T}_{[P_0P_1]}$. We suppose that the origin of the effective 4-velocity vector $\vec{u}_{\text{eff}}$ is placed at the point P. Let the spatial distance between the points P, P' and P, P'' be l. According to the relation (4.7) we obtain

$$l = \sqrt{-\left|\mathbf{PP}'\right|^2} = \sqrt{-\left|\mathbf{PP}''\right|^2} = r\,(0.5) = \sqrt{\frac{3d}{2}} = \sqrt{\frac{3\hbar}{4bc}} \qquad (6.10)$$

We choose the coordinate system with the origin at the point P and with the time axis directed along the vector $\mathbf{P}_0\mathbf{P}_1$. In the space-time V_{M} in this coordinate system we have covariant components of $\mathbf{P}_0\mathbf{P}_1$

$$\left(\mathbf{P}_0\mathbf{P}_1\right)_k = \{\mu_{\text{d}}c, 0, \} \qquad (6.11)$$

The contravariant coordinates of the 4-velocity of the segment $\mathcal{T}_{\left[P_0'P_1'\right]}$ $\mathbf{x}$ have the form

$$u^k = \left\{u^0, \mathbf{u}\right\} = \left\{\frac{1}{c\sqrt{1-\frac{\mathbf{v}^2}{c^2}}}, -\frac{\mathbf{v}}{c\sqrt{1-\frac{\mathbf{v}^2}{c^2}}}\right\}, \qquad \mathbf{v} = -\frac{2\mathbf{x}}{\mu_{\text{d}}}c \qquad (6.12)$$

where $\mathbf{x}$ are the spatial coordinates of the point P'. The effective 4-velocity at the point P is a sum of contributions of all segments $\mathcal{T}_{\left[P_0'P_1'\right]}$

$$u_{\text{eff}}^0 = A\int \rho\,(\mathbf{x})\,\delta\left(l^2-\mathbf{x}^2\right)u^0\,(\mathbf{x})\,d\mathbf{x}, \qquad (6.13)$$

$$l = \sqrt{\frac{3\hbar}{4bc}} \qquad (6.14)$$

$$\mathbf{u}_{\text{eff}} = A\int \rho\,(\mathbf{x})\,\delta\left(l^2-\mathbf{x}^2\right)\mathbf{u}\,(\mathbf{x})\,d\mathbf{x} = -A\int \frac{\rho\,(\mathbf{x})\,\delta\left(l^2-\mathbf{x}^2\right)}{\sqrt{1-\left(\frac{2\mathbf{x}}{\mu_{\text{d}}}\right)^2}}\frac{2\mathbf{x}}{\mu_{\text{d}}}d\mathbf{x} \qquad (6.15)$$

where the quantity ρ is the density of world lines in the statistical ensemble, and the quantity A is determined from the condition of normalization of $\vec{u}_{\text{eff}}\,(P)$

$$c^2\left(u_{\text{eff}}^0\right)^2 - \mathbf{u}_{\text{eff}}^2 = 1 \qquad (6.16)$$

Supposing that $\rho\,(\mathbf{x})$ changes slowly and expanding $\rho\,(\mathbf{x})$ in a series over $\mathbf{x}$, we obtain from (6.13), (6.15)

$$u_{\text{eff}}^0 = A\int \frac{\rho}{c\sqrt{1-\left(\frac{2\mathbf{x}}{\mu_{\text{d}}}\right)^2}}\delta\left(l^2-\mathbf{x}^2\right)d\mathbf{x} = \frac{2\pi A\rho l}{c\sqrt{1-\left(\frac{2l}{\mu_{\text{d}}}\right)^2}} \qquad (6.17)$$

$$\mathbf{u}_{\text{eff}} = -A\int \frac{(\mathbf{x}\boldsymbol{\nabla})\,\rho}{\sqrt{1-\left(\frac{2\mathbf{x}}{\mu_{\text{d}}}\right)^2}}\delta\left(l^2-\mathbf{x}^2\right)\frac{2\mathbf{x}}{\mu_{\text{d}}}c\,d\mathbf{x} = -\frac{4\pi A l^3\boldsymbol{\nabla}\rho}{3\mu_{\text{d}}\sqrt{1-\left(\frac{2l}{\mu_{\text{d}}}\right)^2}} \qquad (6.18)$$

where ρ is the value of the density at the point P. Substituting (6.17), (6.18) in (6.16) and using (6.14), we obtain

$$A=\frac{\sqrt{1-\left(\frac{2l}{\mu_{\mathrm{d}}}\right)^2}}{2\pi l\rho\sqrt{1-\left(\frac{\hbar}{2m_{\mathrm{d}}c}\boldsymbol{\nabla}\ln\rho\right)^2}} \tag{6.19}$$

Substituting (6.19) in (6.17), we obtain

$$u_{\mathrm{eff}}^0=\frac{1}{c\sqrt{1-\left(\frac{\hbar}{2m_{\mathrm{d}}c}\boldsymbol{\nabla}\ln\rho\right)^2}} \tag{6.20}$$

It follows from (6.9), (6.11) and (6.20)

$$m_{\mathrm{eff}}=m_{\mathrm{d}}cu_{\mathrm{eff}}^0=m_{\mathrm{d}}\frac{1}{\sqrt{1-\left(\frac{\hbar}{2m_{\mathrm{d}}c}\boldsymbol{\nabla}\ln\rho\right)^2}}=m_{\mathrm{d}}\left(1+\frac{\hbar^2}{8m_{\mathrm{d}}^2c^2}\left(\boldsymbol{\nabla}\ln\rho\right)^2\right) \tag{6.21}$$

This result coincides with the relation (5.39).

We admit that there are another methods of calculation of the value of m_{eff}, which give another result. In this case we should choose another world function of the space-time V_{d}, which leads to the result (6.21), because we know that the effective mass, determined by the relation (6.21) agrees with the experimental data. We know about the distorted space-time geometry only that it generates stochastic motion of free particles. Information on its world function is obtained from the demand that the world function leads to the effective mass, which is determined by the relation (6.21).

Further development of the statistical description of geometrical stochasticity leads to a creation of the model conception of quantum phenomena (MCQP), which relates to the conventional quantum theory approximately in the same way as the statistical physics relates to the axiomatic thermodynamics. MCQP is the well defined relativistic conception with effective methods of investigation [14], whereas the conventional quantum theory is not well defined, because it uses incorrect space-time geometry, whose incorrectness is compensated by additional hypotheses (quantum principles). Besides, it has problems with application of the nonrelativistic quantum mechanics technique to the description of relativistic phenomena.

The geometry $\mathcal{G}_{\mathrm{d}}$ is a homogeneous geometry as well as the Minkowski geometry, because the world function σ_{d} is invariant with respect to all coordinate transformations, with respect to which the world function σ_{M} is invariant. In this connection the question arises, whether one could invent some axiomatics for $\mathcal{G}_{\mathrm{d}}$ and derive the geometry $\mathcal{G}_{\mathrm{d}}$ from this axiomatics by means of proper reasonings. Note that such an axiomatics is to depend on the parameter d, because the world function σ_{d} depends on this parameter. If $d=0$, this axiomatics is to coincide with the axiomatics of the Minkowski geometry $\mathcal{G}_{\mathrm{M}}$. If $d\neq 0$, this axiomatics cannot coincide with the axiomatics of $\mathcal{G}_{\mathrm{M}}$, because some axioms of $\mathcal{G}_{\mathrm{M}}$ are not satisfied in this case. In general, the invention of axiomatics, depending on the parameter d and in the general case on the distortion function D, seems to be a very difficult problem. Besides, why invent the axiomatics? We had derived the axiomatics for the proper Euclidean geometry, when we constructed it before. There is no necessity to repeat this process any time, when we construct a new geometry. It is sufficient to apply the deformation principle to the constructed Euclidean geometry written σ-immanently. Application of the deformation principle to the Euclidean geometry is a very simple and general procedure, which is not restricted by continuity, convexity and other artificial constraints, generated by our preconceived approach to the physical geometry. (Bias of the approach is displayed in the antecedent supposition on the one-dimensionality of any straight line in any physical geometry, which reminds the statement of the ancient Egyptians that all rivers flow towards the North).

Thus, we have seen that the nondegeneracy of the physical geometry as well as non-one-dimensionality of the straight line are properties of the real physical geometries. The proper Euclidean geometry is a ground for all physical geometries. Although it is a degenerate geometry, it is beyond reason to deny an existence of nondegenerate physical geometries.

Thus, the deformation principle together with the σ-immanent description appears to be a very effective mathematical tool for construction of physical geometries.

1. The deformation principle uses results obtained at construction of the proper Euclidean geometry and does not add any additional supposition on properties of geometrical objects.

2. The deformation principle uses only the real characteristic of the physical geometry – its world function and does not use any additional means of description.

3. The deformation principle is very simple and allows one to investigate only that part of geometry which one is interested in.

4. Application of the deformation principle allows one to obtain the true space-time geometry, whose unexpected properties cannot be obtained at the conventional approach to physical geometry.

Appendix A. Transformation of the action for the statistical ensemble.

To transform the action (5.16) to the description in terms of the wave function, we rewrite it in the form

$$\mathcal{E}_{\mathrm{st}}\left[\mathcal{S}_{\mathrm{st}}\right]: \qquad \mathcal{A}_{\mathcal{E}_{\mathrm{st}}\left[\mathcal{S}_{\mathrm{st}}\right]}\left[\mathbf{x}\right]=\int\left\{\frac{m}{2}\left(\frac{d\mathbf{x}}{dt}\right)^{2}-\frac{\hbar^{2}}{8m}\frac{\left(\boldsymbol{\nabla}\rho\right)^{2}}{\rho^{2}}\right\}dtd\boldsymbol{\xi} \tag{A.1}$$

where

$$\rho=\frac{\partial\left(\xi_1,\xi_2,\xi_3\right)}{\partial\left(x^1,x^2,x^3\right)}=\left(\frac{\partial\left(x^1,x^2,x^3\right)}{\partial\left(\xi_1,\xi_2,\xi_3\right)}\right)^{-1} \tag{A.2}$$

We introduce the independent variable ξ_0 instead of the variable $t=x^0$ and rewrite the action (A.1) in the form

$$\mathcal{A}_{\mathcal{E}_{\rm st}[\mathcal{S}_{\rm st}]}\left[x\right]=\int\left\{\frac{m\dot{x}^\alpha\dot{x}^\alpha}{2\dot{x}^0}-\frac{\hbar^2}{8m}\frac{\left(\boldsymbol{\nabla}\rho\right)^2}{\rho^2}\right\}d^4\xi,\qquad \dot{x}^k\equiv\frac{\partial x^k}{\partial\xi_0} \tag{A.3}$$

where $\xi=\{\xi_0,\boldsymbol{\xi}\}=\{\xi_k\}$, $k=0,1,2,3$, $x=\left\{x^k\left(\xi\right)\right\}$, $k=0,1,2,3$. Here and in what follows, a summation over repeated Greek indices is produced $(1-3)$.

Let us consider variables $\xi=\xi\left(x\right)$ in (A.3) as dependent variables and variables x as independent variables. Let the Jacobian

$$J=\frac{\partial\left(\xi_0,\xi_1,\xi_2,\xi_3\right)}{\partial\left(x^0,x^1,x^2,x^3\right)}=\det\left|\left|\xi_{i,k}\right|\right|,\qquad \xi_{i,k}\equiv\partial_k\xi_i,\qquad i,k=0,1,2,3 \tag{A.4}$$

be considered to be a multilinear function of $\xi_{i,k}$. Then

$$d^4\xi=Jd^4x,\qquad \dot{x}^i\equiv\frac{\partial x^i}{\partial\xi_0}\equiv\frac{\partial\left(x^i,\xi_1,\xi_2,\xi_3\right)}{\partial\left(\xi_0,\xi_1,\xi_2,\xi_3\right)}=J^{-1}\frac{\partial J}{\partial\xi_{0,i}},\qquad i=0,1,2,3 \tag{A.5}$$

After transformation to dependent variables ξ the action (A.3) takes the form

$$\mathcal{A}_{\mathcal{E}_{\rm st}[\mathcal{S}_{\rm st}]}\left[\xi\right]=\int\left\{\frac{m}{2}\frac{\partial J}{\partial\xi_{0,\alpha}}\frac{\partial J}{\partial\xi_{0,\alpha}}\left(\frac{\partial J}{\partial\xi_{0,0}}\right)^{-1}-\frac{\hbar^2}{8m}\frac{\left(\boldsymbol{\nabla}\rho\right)^2}{\rho}\right\}d^4x, \tag{A.6}$$

Here the dependent variable ξ_0 is fictitious

We introduce new variables

$$j^k=\frac{\partial J}{\partial\xi_{0,k}},\qquad k=0,1,2,3,\qquad \rho=j^0 \tag{A.7}$$

by means of Lagrange multipliers p_k

$$\mathcal{A}_{\mathcal{E}_{\rm st}[\mathcal{S}_{\rm st}]}\left[\xi,j,p\right]=\int\left\{\frac{m}{2}\frac{j^\alpha j^\alpha}{j^0}-\frac{\hbar^2}{8m}\frac{\left(\boldsymbol{\nabla}\rho\right)^2}{\rho}+p_k\left(\frac{\partial J}{\partial\xi_{0,k}}-j^k\right)\right\}d^4x, \tag{A.8}$$

Here and in what follows, a summation over repeated Latin indices is produced $(0-3)$.

Note that according to (A.5), the relations (A.7) can be written in the form

$$j^k=\left\{\frac{\partial J}{\partial\xi_{0,0}},\frac{\partial J}{\partial\xi_{0,0}}\left(J^{-1}\frac{\partial J}{\partial\xi_{0,\alpha}}\right)\left(J^{-1}\frac{\partial J}{\partial\xi_{0,0}}\right)^{-1}\right\}=\left\{\rho,\rho\frac{dx^\alpha}{dt}\right\},\qquad \rho\equiv\frac{\partial J}{\partial\xi_{0,0}} \tag{A.9}$$

It is clear from (A.9) that j^k is the 4-flux of particles, with $j^0=\rho$ being its density.

Variation of (A.8) with respect to ξ_i gives

$$\frac{\delta\mathcal{A}_{\mathcal{E}_{\rm st}[\mathcal{S}_{\rm st}]}}{\delta\xi_i}=-\partial_l\left(p_k\frac{\partial^2 J}{\partial\xi_{0,k}\partial\xi_{i,l}}\right)=-\frac{\partial^2 J}{\partial\xi_{0,k}\partial\xi_{i,l}}\partial_l p_k=0,\qquad i=0,1,2,3 \tag{A.10}$$

Using identities

$$\frac{\partial^2 J}{\partial\xi_{0,k}\partial\xi_{i,l}}\equiv J^{-1}\left(\frac{\partial J}{\partial\xi_{0,k}}\frac{\partial J}{\partial\xi_{i,l}}-\frac{\partial J}{\partial\xi_{0,l}}\frac{\partial J}{\partial\xi_{i,k}}\right) \tag{A.11}$$

$$\frac{\partial J}{\partial\xi_{i,l}}\xi_{k,l}\equiv J\delta_k^i,\qquad \partial_l\frac{\partial^2 J}{\partial\xi_{0,k}\partial\xi_{i,l}}\equiv 0 \tag{A.12}$$

one can test by direct substitution that the general solution of linear equations (A.10) has the form

$$p_k=\frac{b_0}{2}\left(\partial_k\varphi+g^\alpha\left(\boldsymbol{\xi}\right)\partial_k\xi_\alpha\right),\qquad k=0,1,2,3 \tag{A.13}$$

where $b_0\neq 0$ is an arbitrary constant, $g^\alpha\left(\boldsymbol{\xi}\right),\ \ \alpha=1,2,3$ are arbitrary functions of $\boldsymbol{\xi}=\{\xi_1,\xi_2,\xi_3\}$, and φ is the dynamic variable ξ_0, which ceases to be fictitious. It is the conceptual integration, which allows one to introduce the wave function. Let us substitute (A.13) in (A.8). The term of the form $\partial_k\varphi\partial J/\partial\xi_{0,k}$ is reduced to Jacobian and does not contribute to dynamic equation. The terms of the form $\xi_{\alpha,k}\partial J/\partial\xi_{0,k}$ vanish due to identities (A.12). We obtain

$$\mathcal{A}_{\mathcal{E}_{\rm st}[\mathcal{S}_{\rm st}]}\left[\varphi,\boldsymbol{\xi},j\right]=\int\left\{\frac{m}{2}\frac{j^\alpha j^\alpha}{j^0}-j^kp_k-\frac{\hbar^2}{8m}\frac{\left(\boldsymbol{\nabla}\rho\right)^2}{\rho}\right\}d^4x,\qquad j^0=\rho \tag{A.14}$$

where quantities p_k are determined by the relations (A.13)

Variation of the action (A.14) with respect to j^k gives

$$p_0=-\frac{m}{2}\frac{j^\alpha j^\alpha}{\rho^2}+\frac{\hbar^2}{8m}\left(\frac{\left(\boldsymbol{\nabla}\rho\right)^2}{\rho^2}+2\boldsymbol{\nabla}\frac{\left(\boldsymbol{\nabla}\rho\right)}{\rho}\right) \tag{A.15}$$

$$p_\beta=m\frac{j^\beta}{\rho},\qquad \beta=1,2,3 \tag{A.16}$$

Now we eliminate the variables $\mathbf{j}=\{j^1,j^2,j^3\}$ from the action (A.14), using relation (A.16). We obtain

$$\mathcal{A}_{\mathcal{E}_{\rm st}[\mathcal{S}_{\rm st}]}\left[\rho,\varphi,\boldsymbol{\xi}\right]=\int\left\{-p_0-\frac{p_\beta p_\beta}{2m}-\frac{\hbar^2}{8m}\frac{\left(\boldsymbol{\nabla}\rho\right)^2}{\rho^2}\right\}\rho d^4x, \tag{A.17}$$

where p_k is determined by the relation (A.13).

Now instead of dependent variables $\rho,\varphi,\boldsymbol{\xi}$ we introduce the n-component complex function ψ, defining it by relations (5.23) – (5.25)

The function ψ is constructed of the variable φ, the fluid density ρ and the Lagrangian coordinates $\boldsymbol{\xi}$, considered as functions of $(t, \mathbf{x})$, as follows [12]. The n-component complex function $\psi = \{\psi_\alpha\}, \ \ \alpha = 1, 2, \ldots, n$ is defined by the relations

$$\psi_\alpha = \sqrt{\rho} e^{i\varphi} u_\alpha(\boldsymbol{\xi}), \qquad \psi_\alpha^* = \sqrt{\rho} e^{-i\varphi} u_\alpha^*(\boldsymbol{\xi}), \qquad \alpha = 1, 2, \ldots, n, \tag{A.18}$$

$$\psi^* \psi \equiv \sum_{\alpha=1}^{n} \psi_\alpha^* \psi_\alpha, \tag{A.19}$$

where (*) means the complex conjugate. The quantities $u_\alpha(\boldsymbol{\xi})$, $\alpha = 1, 2, \ldots, n$ are functions of only variables $\boldsymbol{\xi}$, and satisfy the relations

$$-\frac{i}{2} \sum_{\alpha=1}^{n} \left(u_\alpha^* \frac{\partial u_\alpha}{\partial \xi_\beta} - \frac{\partial u_\alpha^*}{\partial \xi_\beta} u_\alpha \right) = g^\beta(\boldsymbol{\xi}), \qquad \beta = 1, 2, 3, \qquad \sum_{\alpha=1}^{n} u_\alpha^* u_\alpha = 1. \tag{A.20}$$

The number n is such a natural number that equations (A.20) admit a solution. In general, n depends on the form of the arbitrary integration functions $\mathbf{g} = \{g^\beta(\boldsymbol{\xi})\}$, $\beta = 1, 2, 3$. The functions $\mathbf{g}$ determine vorticity of the fluid flow.

It is easy to verify that

$$\rho = \psi^* \psi, \qquad \rho p_0 \left(\varphi, \boldsymbol{\xi}\right) = -\frac{ib_0}{2} (\psi^* \partial_0 \psi - \partial_0 \psi^* \cdot \psi) \tag{A.21}$$

$$\rho p_\alpha \left(\varphi, \boldsymbol{\xi}\right) = -\frac{ib_0}{2} (\psi^* \partial_\alpha \psi - \partial_\alpha \psi^* \cdot \psi), \qquad \alpha = 1, 2, 3, \tag{A.22}$$

The variational problem with the action (A.17) appears to be equivalent to the variational problem with the action functional

$$\mathcal{A}_{\mathcal{E}_{\mathrm{st}}[\mathcal{S}_{\mathrm{st}}]}[\psi, \psi^*] = \int \left\{ \frac{ib_0}{2} (\psi^* \partial_0 \psi - \partial_0 \psi^* \cdot \psi) \right.$$

$$\left. + \frac{b_0^2}{8m\rho} (\psi^* \boldsymbol{\nabla} \psi - \boldsymbol{\nabla} \psi^* \cdot \psi)^2 - \frac{\hbar^2}{8m} \frac{(\boldsymbol{\nabla} \rho)^2}{\rho} \right\} \mathrm{d}^4 x. \tag{A.23}$$

We hope that in the case $n = 2$ equations (A.20) have a solution for any functions $\mathbf{g}$, because in this case the number (four) of real components of ψ coincides with the number of hydrodynamic variables j^k $(k = 0, , 2, 3)$. (But this statement is not yet proved). For the two-component function ψ $(n = 2)$ the following identity takes place

$$(\boldsymbol{\nabla} \rho)^2 - (\psi^* \boldsymbol{\nabla} \psi - \boldsymbol{\nabla} \psi^* \cdot \psi)^2 \equiv 4\rho \boldsymbol{\nabla} \psi^* \boldsymbol{\nabla} \psi - \rho^2 \sum_{\alpha=1}^{\alpha=3} \left(\boldsymbol{\nabla} s_\alpha\right)^2, \tag{A.24}$$

$$\rho \equiv \psi^* \psi, \qquad s \equiv \frac{\psi^* \boldsymbol{\sigma} \psi}{\rho}, \qquad \boldsymbol{\sigma} = \{\sigma_\alpha\}, \qquad \alpha = 1, 2, 3, \tag{A.25}$$

where σ_α are the Pauli matrices. In virtue of the identity (A.24) the action (A.23) reduces to the form

$$\mathcal{E}_{\mathrm{st}}\left[\mathcal{S}_{\mathrm{st}}\right] \quad : \qquad \mathcal{A}_{\mathcal{E}_{\mathrm{st}}[\mathcal{S}_{\mathrm{st}}]}\left[\psi,\psi^*\right] = \int \left\{ \frac{ib_0}{2}\left(\psi^*\partial_0\psi - \partial_0\psi^*\cdot\psi\right) - \frac{b_0^2}{2m}\boldsymbol{\nabla}\psi^*\boldsymbol{\nabla}\psi \right.$$
$$\left. + \frac{b_0^2}{8m}\sum_{\alpha=1}^{\alpha=3}(\boldsymbol{\nabla}s_\alpha)^2\rho + \frac{b_0^2-\hbar^2}{8\rho m}(\boldsymbol{\nabla}\rho)^2 \right\} d^4x, \tag{A.26}$$

where $\mathbf{s}$ and ρ are defined by the relations (A.25). Thus, we prove the relation (5.20).
